## PREFACE

---

The World Health Organization (WHO) estimates that globally 40 million children suffer from violence, and in the Region of the Americas and the Caribbean this includes all types of violence. The majority of minors who endure corporal punishment are between the ages of 2 and 7, and of these the most severely affected are between the ages of 3 and 5. Eighty-five percent of the deaths from abuse and maltreatment are reported as accidental or undetermined. For each death, it is estimated that 9 children are incapacitated; 71 million children suffer from serious injuries and innumerable victims with psychological sequelae. Child abuse and maltreatment includes all forms and physical and/or emotional ill-treatment, sexual abuse, neglect or negligent treatment, commercial or other exploitation, resulting in actual or potential harm to the child's health, survival, development or dignity in the context of a relationship of responsibility, trust, or power.

Current data indicates that child abuse affects the physical health and development of thousands of children in Latin America and the Caribbean, beckoning the necessity for increased efforts in its identification, prevention and treatment, as well as in knowledge regarding its magnitude and research methodologies. The Integrated Management of Childhood Illnesses (IMCI) Strategy set forth by the Pan American Health Organization (PAHO) is one of tools currently available to respond to this need. IMCI contains information on prevention, promotion, evaluation, classification, and treatment of the major diseases and health issues that affect children during their first years of life, with the objective to reduce the risk of disease and to promote health, growth, and development during childhood.

IMCI adaptable to diverse realities, and therefore its contents can be modified to respond to the particular epidemiological patterns in each country, allowing for the inclusion of additional modules, including child abuse and maltreatment

The Child and Adolescent Health Unit of the Family and Community Health Area, in conjunction with the Risk Unit of the Sustainable Development and Environmental Area, of PAHO, has intensified work in capacity building and dissemination of the "Detection and Prevention of Child Abuse and Sexual Abuse of Children en the framework of IMCI" module. This document looks to fill the existing gap in the preparation of health care providers to detect and care for children victims of abuse and maltreatment

While there have been advances in advocacy and national and municipal plans to protect children and reduce abuse and, maltreatment it still is not possible to affirm that these have resulted in social, family, and institutional change. In line with the United Nations Report, in which it is stated that "no form of violence against children is acceptable," PAHO/WHO leads efforts and supports processes and projects. One such effort is the PAHO/GTZ interprogrammatic initiative "Promoting Youth Development and Violence Prevention" which has acted in Nicaragua, El Salvador, Honduras, Colombia, Peru, and Argentina since 2003 with financing by the German government (BMZ). Through this initiative there has been significant progress in the identification of a conceptual framework that supports the promotion of youth development and the prevention of violence, the systematization of effective practices, and the accumulation of evidence in youth development and violence prevention in Latin America.

Furthermore, based on these inputs, PAHO/GTZ has developed TEACH VIP Youth, a capacity building program available as a CD-Rom, an online course, or as a workshop. TEACH VIP Youth aims to improve the design and the evaluation of violence prevention programs. In addition, through this initiative national and local networks have been strengthened with participation of young people, training, and guided the decision-making on what interventions should or should not be considered for implementation. The

evidence documents elaborated through this initiative and the examples of cases can be reviewed at <http://www.paho.org/CDMEDIA/FCHGTZ/docsregionalesdocs.htm>.

The Networks of Buen Trato [Good Treatment] that function in several countries have been used to improve the responses to the problem. This type of network includes government and non-governmental entities and tries to strengthen the capacities and efficiency of each entity joining the effort. For example, experiences such as the "Casa Hogar UNACARI" (meaning the "his house" in the Yaqui dialect) in Hermosillo, Sonora, México, where nearly 200 boys and girls between the ages of 0 and 14 years old have suffered violence or have been abandoned by their mothers and fathers, provides shelter and comprehensive assistance that includes formal education, medical services, psychological support and recreation, in addition to the search for adoptive parents who will provide them with an adequate education and attention. ([http://www.difson.gob.mx/Sitio/programas\\_menores.aspx?prog=pUNACARI](http://www.difson.gob.mx/Sitio/programas_menores.aspx?prog=pUNACARI)).

Aware of the problem and for the need for information on the subject, in 2002 PAHO published the first bibliographic compendium on child abuse and maltreatment which includes more than 700 references and their respective summaries from publications from 1995 to 2000. Through the publication of this second volume of the Bibliography on Child Abuse and maltreatment, the Units of Child and Adolescent Health and Risk Assessment of PAHO wish continue contributing to the promotion of information and evidence on the situation of the child abuse in the Region of the Americas. For this second edition, publications from the years 2001 to 2005 have been compiled from MEDLINE, LILACS and other sources.

The first part of this publication concentrates on articles about the definition, signs, and symptoms of various forms of abuse and maltreatment; the following section contains references on the detection, diagnosis, and evaluation of the utility of these for providers who work with abused children; articles on practices and interventions have been grouped in order to facilitate their search for decision makers and researchers; publications on pornography and child sexual abuse, and other special topics such as street children, displaced persons due to wars and conflicts are listed after a section on the effects of the abuse and neglect, which includes publications on mental health, long-term effects of violence or abuse, resiliency, and aggressive behaviors. The last section compiles publications on human rights, laws, ethics, and policy. A list of Web pages is included at the end of the document.

This publication is for physicians, government institutions, and ministries of health, family, and child protection, academics, professors, researchers, and providers. We hope that it will contribute to the health and development of children, adolescents, and their families and provide additional support for efforts to reach the United Nations Millennium Development Goals (MDGs).

## PRÓLOGO

---

La Organización Mundial de la Salud (OMS) estima que 40 millones de niños sufren violencia en el mundo, y en la Región de las Américas y el Caribe ésta se da en todas sus formas. La mayoría de los menores sometidos a castigos corporales tienen entre 2 y 7 años de edad, y de ellos, el grupo más afectado fluctúa entre los 3 y 5. Un 85% de las muertes por maltrato son clasificadas como accidentales o indeterminadas, y por cada muerte, se calculan 9 incapacitados, 71 niños con lesiones graves e innumerables víctimas con secuelas psicológicas. El abuso o maltrato de menores es toda forma de maltrato físico y/o emocional, abuso sexual, abandono o trato negligente, explotación comercial o de otro tipo, del que resulte un daño real o potencial para la salud, la supervivencia, el desarrollo o la dignidad del niño en el contexto de una relación de responsabilidad, confianza o poder.

La información disponible indica que el maltrato es un problema que afecta la salud física y el desarrollo de miles de niños y niñas en América Latina y el Caribe, por lo cual es necesario avanzar en su detección, prevención y tratamiento, así como en el conocimiento de su magnitud, metodologías de información e investigación. En este sentido, la estrategia de Atención Integrada a las Enfermedades Prevalentes de la Infancia (AIEPI) de la Organización Panamericana de la Salud es una de las mejores herramientas disponibles en la actualidad, ya que incluye contenidos de prevención, promoción, evaluación, clasificación y tratamiento de las enfermedades y problemas de salud que con mayor frecuencia afectan a los niños durante sus primeros años de vida, con el objetivo de reducir los riesgos de enfermedad y para fomentar un crecimiento y desarrollo saludables durante la niñez.

La AIEPI se adapta a cada realidad, lo que contribuye a adecuar sus contenidos básicos a los patrones epidemiológicos de morbilidad y mortalidad de cada país, permitiendo incorporar contenidos adicionales. Entre ellos está el maltrato infantil.

Si bien hay avances en materia de abogacía y planes nacionales o municipales para proteger a los niños y niñas y reducir su abuso y maltrato, aún no es posible afirmar que aquello se refleje en transformaciones sociales, familiares e institucionales. Haciendo mención al informe de NNUU que indica que "ninguna forma de violencia contra la niñez es aceptable", OPS/OMS ha dirigido esfuerzos y ha apoyado procesos y proyectos, como OPS/GTZ que existe desde 2003 con financiamiento del Gobierno Alemán (BMZ). A través de él se ha implementado la iniciativa interprogramática de "Fomento del Desarrollo Juvenil y Prevención de la Violencia" en Nicaragua, El Salvador, Honduras, Colombia, Perú y Argentina, avanzándose significativamente en la identificación de un marco conceptual que apoye la promoción del desarrollo de los jóvenes y la prevención de la violencia, la sistematización de las prácticas exitosas, y la acumulación de evidencias sobre desarrollo juvenil y prevención de violencia en países de América Latina.

Asimismo, en base a estos insumos se ha desarrollado el curso de capacitación TEACH VIP Youth (en CD, Internet y presencial), destinado a mejorar el diseño y la evaluación de programas efectivos para la prevención de la violencia. Con esta iniciativa se han reforzado además las redes nacionales y locales con participación de jóvenes, capacitando y orientado la toma de decisiones sobre qué intervenciones deben ser o no consideradas para ser implementadas. Los documentos de evidencia de este proyecto y los ejemplos de casos se pueden revisar en <http://www.paho.org/CDMEDIA/FCHGTZ/docsregionalesdocs.htm>

Las Redes del Buen Trato que existen en varios países han servido para avanzar en la perspectiva de modificar la forma de atender el problema. Este tipo de redes incluyen a entidades de gobierno y no gubernamentales y buscan fortalecer las capacidades y eficiencia de cada entidad sumando esfuerzos. Experiencias como la Casa Hogar UNACARI (que significa "La casa de él" en dialecto Yaqui) en curso en

Hermosillo, Sonora, México, donde cerca de 200 niños y niñas de 0 a 14 años -que han sufrido violencia o han sido abandonados por sus madres y padres- disponen de albergue y asistencia integral que incluye educación formal, servicios médicos, apoyo psicológico y recreación, además de la búsqueda de padres adoptivos que les garanticen una adecuada educación y atención.

([http://www.difson.gob.mx/Sitio/programas\\_menores.aspx?prog=pUNACARI](http://www.difson.gob.mx/Sitio/programas_menores.aspx?prog=pUNACARI)).

Por esa razón, la Unidad de Salud del Niño y del Adolescente, Área Salud Familiar y Comunitaria, en conjunto con la Unidad de Riesgos, Programa de Prevención de Violencia y Lesiones, de OPS, ha intensificado el trabajo de capacitación y difusión del Módulo "Detección y prevención del maltrato infantil y abuso sexual en la niñez en el marco de AIEPI". Este documento busca llenar el vacío que aún existe en la preparación del personal de salud para detectar y tratar los niños víctimas de maltrato o abuso. Asimismo, en 2002 se publicó el primer compendio bibliográfico sobre maltrato y abuso infantil con más de 700 referencias, con sus respectivos resúmenes, correspondientes a publicaciones del período 1995 - 2000.

Con este segundo volumen de Bibliografía sobre Maltrato y Abuso Infantil, las Unidades de Salud del Niño y del Adolescente y de Prevención de Violencia de la OPS, desean contribuir a promover información y evidencia sobre la situación del maltrato infantil en la Región de las Américas. Para ello se han recopilado publicaciones de los años 2001 a 2005, tomadas de MEDLINE, LILACS y otras fuentes.

La primera parte se concentra en artículos sobre definición, signos y síntomas de diversas formas de abuso y maltrato; en el siguiente bloque se recopilan referencias sobre detección, diagnóstico y evaluación de utilidad práctica para quienes atienden a los niños y niñas maltratados; los artículos sobre prácticas e intervenciones se han agrupado para facilitar su búsqueda a tomadores de decisiones e investigadores; las publicaciones sobre pornografía y abuso sexual infantil, y otros como niños de la calle, desplazados de guerras y conflictos se enumeran después de los efectos del abuso y el maltrato, que recoge publicaciones sobre salud mental, efectos de larga duración en casos de violencia o maltrato, resiliencia y conductas agresivas. En la última parte se agruparon publicaciones sobre derechos humanos, leyes, ética y política. Una lista de páginas de Internet se añade al final.

Esta publicación está destinada a médicos, instituciones de gobierno, ministerios de salud, de familia y de protección de la niñez, académicos, profesores, investigadores y proveedores, y esperamos que sea un aporte para el desarrollo y la salud de los niños, adolescentes y sus familias, y una forma de alcanzar los Objetivos de Desarrollo del Milenio (ODM) de las Naciones Unidas.

The assessment and management of acute pain in infants, children, and adolescents. *Pediatrics* 2001; 108(3):793-7.

Notes: CORPORATE NAME: American Academy of Pediatrics. Committee on Psychosocial Aspects of Child and Family Health  
CORPORATE NAME: Task Force on Pain in Infants, Children, and Adolescents

Abstract: Acute pain is one of the most common adverse stimuli experienced by children, occurring as a result of injury, illness, and necessary medical procedures. It is associated with increased anxiety, avoidance, somatic symptoms, and increased parent distress. Despite the magnitude of effects that acute pain can have on a child, it is often inadequately assessed and treated. Numerous myths, insufficient knowledge among caregivers, and inadequate application of knowledge contribute to the lack of effective management. The pediatric acute pain experience involves the interaction of physiologic, psychologic, behavioral, developmental, and situational factors. Pain is an inherently subjective multifactorial experience and should be assessed and treated as such. Pediatricians are responsible for eliminating or assuaging pain and suffering in children when possible. To accomplish this, pediatricians need to expand their knowledge, use appropriate assessment tools and techniques, anticipate painful experiences and intervene accordingly, use a multimodal approach to pain management, use a multidisciplinary approach when possible, involve families, and advocate for the use of effective pain management in children.

GENERAL NOTE: KIE: 30 refs.  
GENERAL NOTE: KIE: KIE Bib: informed consent/minors

Abstract: Pediatric patients frequently seek medical treatment in the emergency department (ED) unaccompanied by a legal guardian. Current state and federal laws and medical ethics recommendations support the ED treatment of minors with an identified emergency medical condition, regardless of consent issues. Financial reimbursement should not limit the minor patient's access to emergency medical care or result in a breach of patient confidentiality. Every clinic, office practice, and ED should develop policies and guidelines regarding consent for the treatment of minors. The physician should document all discussions of consent and attempt to seek consent for treatment from the family or legal guardian and assent from the pediatric patient. Appropriate medical care for the pediatric patient with an urgent or emergent condition should never be withheld or delayed because of problems with obtaining consent. This statement has been endorsed by the American College of Surgeons, the Society of Pediatric Nurses, the Society of Critical Care Medicine, the American College of Emergency Physicians, the Emergency Nurses Association, and the National Association of EMS Physicians.

Drugs for the doctor's bag: 2--children. *Drug Ther Bull* 2005; 43(11):81-4.

Abstract: In September 2005, we published *Drugs for the doctor's bag: 1--Adults*, recognising the fact that there is still a need for most GPs to carry well-equipped bags, even though many have given up responsibility for out-of-hours services. Here we suggest medicines that a GP might want to have available for use in an emergency or for the acute treatment of children and adolescents, updating our previous advice. As with adults, it is not our intention to imply that every GP must carry every drug mentioned. Some of the drugs will probably only be used by rural GPs who do not have access to immediate emergency care. Whenever a medicine is first mentioned, our suggested formulation is included in brackets. Unless otherwise stated, the doses given are all from the BNF for Children. We enclose with this issue a card summarising parenteral doses (for adults and children) of drugs for medical emergencies; this card includes the BNF table of ideal weight for age.

The implementation of the Fast Track program: an example of a large-scale prevention science efficacy trial. *J Abnorm Child Psychol* 2002; 30(1):1-17. Abstract: In 1990, the Fast Track Project was initiated to evaluate the feasibility and effectiveness of a comprehensive, multicomponent prevention program targeting children at risk for conduct disorders in four demographically diverse American communities (Conduct Problems Prevention Research Group [CPPRG], 1992). Representing a prevention science approach toward community-based preventive intervention, the Fast Track intervention design was based upon the available data base elucidating the epidemiology of risk for conduct disorder and suggesting key causal developmental influences (R. P. Weissberg & M. T. Greenberg, 1998). Critical questions about this approach to prevention center around the extent to which such a science-based program can be effective at (1) engaging community members and stakeholders, (2) maintaining intervention fidelity while responding appropriately to the local norms and needs of communities that vary widely in their demographic and cultural/ethnic composition, and (3) maintaining community engagement in the long-term to support effective and sustainable intervention dissemination. This paper discusses these issues, providing examples from the Fast Track project to illustrate the process of program implementation and the evidence available regarding the success of this science-based program at engaging communities in sustainable and effective ways as partners in prevention programming.

Management of child abuse in Hong Kong: results of a territory-wide inter-hospital prospective surveillance study. *Hong Kong Med J* 2003; 9(1):6-9. Notes: CORPORATE NAME: Hong Kong Medical Coordinators on Child Abuse Abstract: OBJECTIVES: To study suspected child abuse among children in hospital in terms of clinical characteristics and the outcome of multidisciplinary case conferences. DESIGN: Prospective observational study. SETTING: All public hospitals in Hong Kong with a paediatric department. METHODS: Anonymous data were prospectively collected from July 1997 to June 1999 using a standard report form for each case of suspected child abuse. The characteristics of the incidents and factors influencing the conclusion at the multidisciplinary case conference were studied. RESULTS: Data for 592 cases of suspected child abuse were evaluated. Two hundred and eighty-seven of the children were boys and 305 were girls. The mean age was 7.3 years (range, 0-16.7 years). Physical abuse, alone or in combination with other forms of maltreatment, accounted for 277 (86.6%) of the 320 substantiated cases. Either, or both, biological parents comprised 71.3% of the perpetrators. Seven (1.2%) children died. Of the 540 children about whom a multidisciplinary case conference was held, abuse was established for 281 (52.0%) children. Abuse was more likely to be established if the victim had been known to a childcare agency (odds ratio=2.2; 95% confidence interval, 1.4-3.5), the abuse was not sexual (odds ratio=2.7; 95% confidence interval, 1.4-5.0), or if the child was seen at a hospital that handled more than 100 cases of suspected abuse during the study period (odds ratio=3.6; 95% confidence interval, 2.4-5.4). CONCLUSION: Child abuse identified in the hospital setting is predominantly physical in nature and death is not uncommon. Appraisal of suspected child abuse by multidisciplinary case conference appears to be influenced by the region of Hong Kong in which the case was handled.

Out-of-school suspension and expulsion. *American Academy of Pediatrics Committee on School Health. Pediatrics* 2003; 112(5):1206-9. Notes: CORPORATE NAME: American Academy of Pediatrics Committee on School Health Abstract: Suspension and expulsion from school are used to punish students, alert parents, and protect other students and school staff. Unintended consequences of these practices require more attention from health care professionals. Suspension and expulsion may exacerbate academic deterioration, and when students are provided with no immediate educational alternative, student alienation, delinquency, crime, and substance abuse may ensue. Social, emotional, and mental health support for students at all times in all schools can decrease the need for expulsion and suspension and should be strongly advocated by the health care community. This policy statement, however, highlights aspects of expulsion and suspension that jeopardize children's health and safety. Recommendations are targeted at pediatricians, who can help schools address the root causes of behaviors that lead to suspension and expulsion and can advocate for alternative disciplinary policies. Pediatricians can also share responsibility with schools to provide students with health and social resources.

The Pediatrician's role in family support programs. *Committee on Early Childhood and Adoption, and Dependent Care. Pediatrics* 2001; 107(1):195-7. Notes: CORPORATE NAME: American Academy of Pediatrics. Committee on Early Childhood and Adoption, and Dependent Care Abstract: Children's brain growth, general health, and development are directly influenced by emotional relationships during early childhood. Contemporary American life challenges families' abilities to promote successful developmental outcomes and emotional health for their children. Pediatricians are positioned to serve as family advisors and community partners in supporting the well-being of children and families. This statement recommends opportunities for pediatricians to develop their expertise in assessing the strengths and stresses in families, in counseling families about strategies and resources, and in

collaborating with others in their communities to support family relationships.

Poison treatment in the home. American Academy of Pediatrics Committee on Injury, Violence, and Poison Prevention. *Pediatrics* 2003; 112(5):1182-5. Notes: CORPORATE NAME: American Academy of Pediatrics Committee on Injury, Violence, and Poison Prevention

Abstract: The ingestion of a potentially poisonous substance by a young child is a common event, with the American Association of Poison Control Centers reporting approximately 1.2 million such events in the United States in 2001. The American Academy of Pediatrics (AAP) has long concerned itself with this issue and has made poison prevention an integral component of its injury prevention initiatives. A key AAP recommendation has been to keep a 1-oz bottle of syrup of ipecac in the home to be used only on the advice of a physician or poison control center. Recently, there has been interest regarding activated charcoal in the home as a poison treatment strategy. After reviewing the evidence, the AAP believes that ipecac should no longer be used routinely as a home treatment strategy, that existing ipecac in the home should be disposed of safely, and that it is premature to recommend the administration of activated charcoal in the home. The first action for a caregiver of a child who may have ingested a toxic substance is to consult with the local poison control center.

Predictor variables associated with positive Fast Track outcomes at the end of third grade. *J Abnorm Child Psychol* 2002; 30(1):37-52.

Abstract: Progress has been made in understanding the outcome effects of preventive interventions and treatments designed to reduce children's conduct problems. However, limited research has explored the factors that may affect the degree to which an intervention is likely to benefit particular individuals. This study examines selected child, family, and community baseline characteristics that may predict proximal outcomes from the Fast Track intervention. The primary goal of this study was to examine predictors of outcomes after 3 years of intervention participation, at the end of 3rd grade. Three types of proximal outcomes were examined: parent-rated aggression, teacher-rated oppositional-aggressive behavior, and special education involvement. The

relation between 11 risk factors and these 3 outcomes was examined, with separate regression analyses for the intervention and control groups. Moderate evidence of prediction of outcome effects was found, although none of the baseline variables were found to predict all 3 outcomes, and different patterns of prediction emerged for home versus school outcomes.

Prevalence of anemia among displaced and nondisplaced mothers and children--Azerbaijan, 2001. *MMWR Morb Mortal Wkly Rep* 2004; 53(27):610-4. Notes: CORPORATE NAME: Centers for Disease Control and Prevention (CDC)

Abstract: In the early 1990s, the war between Armenia and Azerbaijan over the Azeri region of Nagorno-Karabakh resulted in approximately 600,000 internally displaced persons and 200,000 refugees in Azerbaijan. After years of displacement and despite sustained humanitarian assistance, these internally displaced persons and refugees (IDP/Rs) are still coping with unfavorable living conditions and limited employment opportunities. Results of a 1996 CDC survey in Azerbaijan revealed high rates of malnutrition and anemia among both the IDP/R and resident populations and prompted further study of the nutritional status of these populations. This report summarizes results of a 2001 survey of IDP/R and non-IDP/R mothers and children with anemia in Azerbaijan. Findings indicated that more than one third of mothers and children were anemic, with no significant difference in the overall prevalence between IDP/R and non-IDP/R populations; however, among the IDP/R population, anemia was associated with various socioeconomic factors such as education, socioeconomic status (SES), and area of residence. Future studies should focus on identifying causes for the high rates of anemia in Azerbaijan and developing effective interventions such as iron supplementation and behavior modification.

Protection of human research subjects. Final rule. *Fed Regist* 2001; 66(219):56775-80.

Notes: CORPORATE NAME: Department of Health and Human Services (DHHS) GENERAL NOTE: KIE: KIE Bib: embryo and fetal research; human experimentation/minors; human experimentation/regulation; human experimentation/special populations

Abstract: The Department of Health and Human Services (DHHS) is withdrawing Subpart B of its human subjects protection regulations published on January 17, 2001 and is issuing this replacement rule. These regulations provide additional protections for pregnant women and human fetuses involved in research. The final rule continues the special protections for pregnant women and human fetuses that have existed since 1975 and makes limited changes in terminology referring to neonates, clarifies provisions for paternal consent when research is conducted involving fetuses, clarifies language that applies to research on newborns of uncertain viability, and

corrects technical errors.

Regional Infant and Child Mortality Review Committee  
2000 final report. *S D J Med* 2001; 54(11):448-51.

Risperidone treatment of autistic disorder: longer-term benefits and blinded discontinuation after 6 months. *Am J Psychiatry* 2005; 162(7):1361-9.  
Notes: CORPORATE NAME: Research Units on Pediatric Psychopharmacology Autism Network  
Abstract: OBJECTIVE: Risperidone is effective for short-term treatment of aggression, temper outbursts, and self-injurious behavior in children with autism. Because these behaviors may be chronic, there is a need to establish the efficacy and safety of longer-term treatment with this agent. METHOD: The authors conducted a multisite, two-part study of risperidone in children ages 5 to 17 years with autism accompanied by severe tantrums, aggression, and/or self-injurious behavior who showed a positive response in an earlier 8-week trial. Part I consisted of 4-month open-label treatment with risperidone, starting at the established optimal dose; part II was an 8-week randomized, double-blind, placebo-substitution study of risperidone withdrawal. Primary outcome measures were the Aberrant Behavior Checklist irritability subscale and the Clinical Global Impression improvement scale. RESULTS: Part I included 63 children. The mean risperidone dose was 1.96 mg/day at entry and remained stable over 16 weeks of open treatment. The change on the Aberrant Behavior Checklist irritability subscale was small and clinically insignificant. Reasons for discontinuation of part I included loss of efficacy (N=5) and adverse effects (N=1). The subjects gained an average of 5.1 kg. Part II included 32 patients. The relapse rates were 62.5% for gradual placebo substitution and 12.5% for continued risperidone; this difference was statistically significant. CONCLUSIONS: Risperidone showed persistent efficacy and good tolerability for intermediate-length treatment of children with autism characterized by tantrums, aggression, and/or self-injurious behavior. Discontinuation after 6 months was associated with a rapid return of disruptive and aggressive behavior in most subjects.

School health guidelines to prevent unintentional injuries and violence. *MMWR Recomm Rep* 2001; 50(RR-22):1-73.

Notes: CORPORATE NAME: Centers for Disease Control and Prevention  
Abstract: Approximately two thirds of all deaths among children and adolescents aged 5-19 years result from injury-related causes: motor-vehicle crashes, all other unintentional injuries, homicide, and suicide. Schools have a responsibility to prevent injuries from occurring on school property and at school-sponsored events. In addition, schools can teach students the skills needed to promote safety and prevent unintentional

injuries, violence, and suicide while at home, at work, at play, in the community, and throughout their lives. This report summarizes school health recommendations for preventing unintentional injury, violence, and suicide among young persons. These guidelines were developed by CDC in collaboration with specialists from universities and from national, federal, state, local, and voluntary agencies and organizations. They are based on an in-depth review of research, theory, and current practice in unintentional injury, violence, and suicide prevention; health education; and public health. Every recommendation is not appropriate or feasible for every school to implement. Schools should determine which recommendations have the highest priority based on the needs of the school and available resources. The guidelines include recommendations related to the following eight aspects of school health efforts to prevent unintentional injury, violence, and suicide: a social environment that promotes safety; a safe physical environment; health education curricula and instruction; safe physical education, sports, and recreational activities; health, counseling, psychological, and social services for students; appropriate crisis and emergency response; involvement of families and communities; and staff development to promote safety and prevent unintentional injuries, violence, and suicide.

Screening HIV-infected persons for tuberculosis--Cambodia, January 2004-February 2005. *MMWR Morb Mortal Wkly Rep* 2005; 54(46):1177-80.  
Notes: CORPORATE NAME: Centers for Disease Control and Prevention (CDC)  
Abstract: Worldwide, tuberculosis (TB) is one of the most common causes of death among persons infected with human immunodeficiency virus (HIV). The World Health Organization recommends screening HIV-infected persons for TB disease after HIV diagnosis, before initiation of highly active antiretroviral therapy (HAART), and during routine follow-up care. In 2003, health officials in Banteay Meanchey Province, Cambodia, in conjunction with CDC and the U.S. Agency for International Development (USAID), began a pilot project to increase TB screening among persons with HIV infection. Subsequently, CDC analyzed and evaluated data from the first 14 months of the project. This report summarizes the results of that analysis, which determined that, during January 2004--February 2005, among persons with HIV infection at voluntary counseling and confidential testing (VCCT) clinics, 37% were screened for TB disease, and 24% of those screened had TB disease diagnosed. On the basis of these findings, the Provincial Health Department (PHD) took action to increase awareness of the risk for TB among HIV-infected persons. During the 3 months after these measures were implemented, the TB screening rate among persons with HIV infection increased to 61%. Evaluation of projects like the one conducted in Banteay Meanchey Province can help

- develop an evidence-based approach for removing barriers to screening HIV-infected persons for TB.

- Abbott D, Townsley R, Watson D. Multi-agency working in services for disabled children: what impact does it have on professionals? *Health Soc Care Community* 2005; 13(2):155-63.
- Abstract: Whilst agencies in many sectors have been encouraged to work together to better meet the needs of service users, multi-agency working is now a central feature of government policy. In relation to children's services, the National Service Framework, the English green paper, 'Every Child Matters' (DfES, 2003) and the Children Bill (DfES 2004) give a high priority to an integrated approach to service provision. This paper focuses on multi-agency working for disabled children with complex health-care needs, a group of children who, perhaps even more than most, require the many professionals who support them and their families, to work more closely together. Drawing on the findings from a 3-year qualitative research study, this paper examines the impact of working in a multi-agency service on professionals. Interviews with 115 professionals concluded that staff were overwhelmingly positive about working as part of a multi-agency service. They reported improvements to their working lives in areas such as professional development, communication, collaboration with colleagues, and relationships with families with disabled children. However, whilst professionals felt that they were able to offer families a more efficient service, there was concern that the overall impact of multi-agency working on disabled children and their families would be limited.

- Abramson JM, Wollan P, Kurland M, Yawn BP. Feasibility of school-based spirometry screening for asthma. *J Sch Health* 2003; 73(4):150-3.  
 Abstract: To determine the feasibility and value of spirometry in school-based asthma screening, spirometry testing was coupled with parent questionnaires in a school-based asthma screening project. Children in grades five to eight of the Catholic school system in Rochester, Minn., performed spirometry with coaching and data acquisition by nurses trained for this activity. Most students completed three tests. For each student, the best test was selected for interpretation. Tests were considered technically unacceptable for screening purposes if the FEV1 was less than 85% and the curve showed evidence of cough, delayed start, poor initial effort, incomplete effort, or non-reproducibility. Students with acceptable tests and FEV1 < 85% as predicted for age, race, and BMI were classified as appropriate for referral for further evaluation of potential asthma. A sensitivity analysis was conducted using different FEV1 thresholds for referral. Children (119, 17.6% of all) with known asthma based on parent-completed questionnaire were not considered for referral. Of the remaining 557 students screened, 535 had technically acceptable tests, and 498 had normal spirometry performance. Using a threshold for referral of FEV1 < 85%, 37 children were candidates for referral for further evaluation of potential asthma. Only four (11%)

of these also had questionnaire responses that made them candidates for referral. School-based spirometry screening for asthma is technically feasible but there is little overlap between those who are referral candidates based on spirometry data and those who are referral candidates based on parent-reported symptoms on screening questionnaires. Without further study, spirometry cannot be recommended for school-based asthma screening.

Abstract: Obstetricians are facing a tide of non-medically indicated requests for cesarean section. Risks and benefits of accepting cesarean section on request are discussed.

Acir N, Oztura I, Kuntalp M, Baklan B, Guzelis C. Automatic detection of epileptiform events in EEG by a three-stage procedure based on artificial neural networks. *IEEE Trans Biomed Eng* 2005; 52(1):30-40.  
Abstract: This paper introduces a three-stage procedure based on artificial neural networks for the automatic detection of epileptiform events (EVs) in a multichannel electroencephalogram (EEG) signal. In the first stage, two discrete perceptrons fed by six features are used to classify EEG peaks into three subgroups: 1) definite epileptiform transients (ETs); 2) definite non-ETs; and 3) possible ETs and possible non-ETs. The pre-classification done in the first stage not only reduces the computation time but also increases the overall detection performance of the procedure. In the second stage, the peaks falling into the third group are aimed to be separated from each other by a nonlinear artificial neural network that would function as a postclassifier whose input is a vector of 41 consecutive sample values obtained from each peak. Different networks, i.e., a backpropagation multilayer perceptron and two radial basis function networks trained by a hybrid method and a support vector method, respectively, are constructed as the postclassifier and then compared in terms of their classification performances. In the third stage, multichannel information is integrated into the system for contributing to the process of identifying an EV by the electroencephalographers (EEGers). After the integration of multichannel information, the overall performance of the system is determined with respect to EVs. Visual evaluation, by two EEGers, of 19 channel EEG records of 10 epileptic patients showed that the best performance is obtained with a radial basis support vector machine providing an average sensitivity of 89.1%, an average selectivity of 85.9%, and a false detection rate (per hour) of 7.5.

Adair PM, Pine CM, Burnside G *et al.* Familial and cultural perceptions and beliefs of oral hygiene and dietary

practices among ethnically and socio-economically diverse groups. *Community Dent Health* 2004; 21(1 Suppl):102-11.

Abstract: OBJECTIVE: The aim of this international study was to develop a valid and reliable psychometric measure to examine the extent to which parents' attitudes about engaging in twice-daily tooth brushing and controlling sugar snacking predict these respective behaviours in their children. A supplementary objective was to assess whether ethnic group, culture, level of deprivation or children's caries experience impact upon the relationships between oral health related behaviours, attitudes to these respective behaviours and to dental caries. CLINICAL SETTING: Nurseries, health centres and dental clinics in 17 countries. PARTICIPANTS: 2822 children aged 3 to 4 years and their parents. MAIN OUTCOME MEASURES: Dental examination of children and questionnaire to parents. RESULTS: Factor analysis identified 8 coherent attitudes towards toothbrushing, sugar snacking and childhood caries. Attitudes were significantly different in families from deprived and non-deprived backgrounds and in families of children with and without caries. Parents perception of their ability to control their children's toothbrushing and sugar snacking habits were the most significant predictor of whether or not favourable habits were reported. Some differences were found by site and ethnic group. CONCLUSIONS: This study supports the hypothesis that parental attitudes significantly impact on the establishment of habits favourable to oral health. An appreciation of the impact of cultural and ethnic diversity is important in understanding how parental attitudes to oral health vary. Further research should examine in a prospective intervention whether enhancing parenting skills is an effective route to preventing childhood caries.

Adams AM, Madhavan S, Simon D. Women's social networks and child survival in Mali. *Soc Sci Med* 2002; 54(2):165-78.

Abstract: This paper explores the influence of women's social networks on child survival through a comparative investigation of two ethnic groups in Mali, West Africa. Data are drawn from a study of women's social networks and health conducted during the period 1996-97. Separate samples of 500 ever-married women aged 15-49 were surveyed at two geographically distinct sites representing Bamanan and Fulbe populations respectively. Consistent with known differences in economic risk, household structure, and cultural norms, descriptive analysis reveals a greater probability of child death among the Fulbe, and a larger mean size of total, material, practical and cognitive networks among the Bamanan. Cox regression models are used to examine the association between social network size, function and composition and the odds of child death (1-5 years). Among the various biological, household and community-level variables tested in the basic model, spacing exerts an

expected negative effect on the odds of child death in both groups, while household SES predicts child survival only among Fulbe children. When variables representing the educational and psychosocial attributes of the mother are included, no effects are detected in either group. Controlling for these factors, the size of total, practical, cognitive and emotional networks are found to significantly increase the odds of child survival among the Fulbe only. Compositional variables, such as the extent to which natal kin, non-kin or husbands figure in a woman's network, nor the degree to which networks are located within household yield any significant results for the Fulbe. Among Bamanan women, however, the higher the proportion of network members living in the household, the lower the odds of child death. The paper concludes by discussing the methodological, conceptual and practical implications of these findings.

Adams JA. Evaluating children for possible sexual abuse. *Am Fam Physician* 2001; 63(5):843-4, 846.

Adams Larsen M, Tentis E. The art and science of disciplining children. *Pediatr Clin North Am* 2003; 50(4):817-40, viii-ix.

Abstract: A practical guide to working with parents on the discipline of their children is provided. Focus is specific to provide a practical tool of useful how-to information for the primary care provider who works with children and their families. This article focuses on basic principles and techniques that can be established within the office setting, so as to model for families, as well as to teach to families for use at home. This article also focuses on common applications to illustrate the use of these techniques. Finally, the art of consultation and referral is reviewed for situations that are assessed to be above and beyond the call of the primary practitioner.

Adams WG, Mann AM, Bauchner H. Use of an electronic medical record improves the quality of urban pediatric primary care. *Pediatrics* 2003; 111(3):626-32. Abstract: OBJECTIVE: To evaluate the quality of pediatric primary care, including preventive services, before and after the introduction of an electronic medical record (EMR) developed for use in an urban pediatric primary care center. METHODS: A pre-postintervention analysis was used in the study. The intervention was a pediatric EMR. Routine health care maintenance visits for children <5 years old were reviewed, and documentation during preintervention (paper-based, 1998) and postintervention visits (computer-based, 2000) was compared. RESULTS: A total of 235 paper-based visits and 986 computer-based visits met study criteria. Twelve clinicians (all attendings or nurse practitioners) contributed an average of 19.4 paper-based visits (range: 5-39) and 7 of these clinicians contributed an average of 141 computer-based visits each (range: 61-213). Computer-

based clinicians were significantly more likely to address a variety of routine health care maintenance topics including: diet (relative risk [RR]: 1.09), sleep (RR: 1.46), at least 1 psychosocial issue (RR: 1.42), smoking in the home (RR: 15.68), lead risk assessment (RR: 106.54), exposure to domestic or community violence (RR: 35.19), guns in the home (RR: 58.11), behavioral or social developmental milestones (RR: 2.49), infant sleep position (RR: 9.29), breastfeeding (RR: 1.99), poison control (RR: 3.82), and child safety (RR: 1.29). Trends toward improved lead exposure, vision, and hearing screening were seen; however, differences were not significant. Users of the system reported that its use had improved the overall quality of care delivered, was well-accepted by families, and improved guidance quality; however, 5 of 7 users reported that eye-to-eye contact with patients was reduced, and 4 of 7 reported that use of the system increased the duration of visits (mean: 9.3 minutes longer). All users recommended continued use of the system. CONCLUSION: Use of the EMR in this study was associated with improved quality of care. This experience suggests that EMRs can be successfully used in busy urban pediatric primary care centers and, as recommended by the Institute of Medicine, must play a central role in the redesign of the US health care system.

Adamsbaum C, Rolland Y, Husson B. [Pediatric neuroimaging emergencies.]. *J Neuroradiol* 2004; 31(4):272-80.

Abstract: The notion of emergency with regards to pediatric neuroimaging requires a strong knowledge of clinical indications. In children under 2 years of age, head trauma requires a CT scan in case of repeated or prolonged or rapidly increasing vomiting, focal signs, loss of consciousness, unusual behavior, seizures, clinical signs of skull fracture or polytrauma. The "shaken baby syndrome" is usually suspected in case of loss of consciousness or seizures before 8 months of age. The hematomas that are observed are subdural in location, diffuse and deeply located. Imaging is only mandatory for headache suggesting underlying space occupying lesion: permanent or increasing pain, nocturnal headache, headache during postural changes or efforts, associated to seizures or abnormal neurological examination. No imaging is indicated in case of first epileptic seizure associated to normal neurological examination and without any particular context. The presence of trauma, intracranial hypertension, persisting disturbances of consciousness or associated focal sign necessitates urgent neuroimaging. No imaging is indicated in case of typical febrile seizures, i.e. generalized, brief and occurring between 1 and 5 years of age. Spinal cord symptoms require immediate MRI evaluation. The most frequent tumor is neuroblastoma. In the absence of spinal tumor, brain abnormalities must be excluded (inflammatory disease). In neonates, CT scan or MRI must be readily performed in case of seizures or loss of

consciousness to exclude ischemic, traumatic or infectious lesions.

Addington J, Addington D. Patterns of premorbid functioning in first episode psychosis: relationship to 2-year outcome. *Acta Psychiatr Scand* 2005; 112(1):40-6. Abstract: OBJECTIVE: To determine how different patterns of premorbid functioning relate to outcome longitudinally. METHOD: Premorbid adjustment was assessed in 194 first-episode of psychosis subjects. Positive and negative symptoms, depression, substance misuse and social and cognitive functioning were assessed over 2 years. RESULTS: Four patterns of premorbid adjustment: stable-good, stable-intermediate, poor-deteriorating and deteriorating were identified. Relative to the stable-good group, the deteriorating and poor-deteriorating groups had significantly more positive symptoms at 1-year follow-up but not at 2-year follow-up and significantly more negative symptoms and significantly poorer social functioning at both 1 and 2-years. Only verbal fluency and memory differentiated between the groups with the stable-good group having a superior performance. CONCLUSION: Those who demonstrated poor or deteriorating functioning prior to the onset of acute psychosis have a poorer outcome up to at least 2 years in terms of negative symptoms and social functioning.

Aden AS, Dahlgren L, Tarsitani G. Gendered experiences of conflict and co-operation in heterosexual relations of Somalis in exile in Gothenburg, Sweden. *Ann Ig* 2004; 16(1-2):123-39.

Abstract: Political upheaval and poverty at home has been forcing many Somalis to immigrate. These immigrants do not only leave their physical house, families, relatives, loved ones, friends, but also familiarities, culture, customs, and often they do end up in no man's land being between their own and new home culture. Available reports suggest that there are about 15,000 Somalis in Sweden and their majority came here from late 1989 to 1996. About one third these immigrants live in and around the city of Gothenburg. This paper explores and describes gendered experiences of conflict and co-operation in heterosexual relations of Somalis in exile in Gothenburg, Sweden. A qualitative sociological in-depth interviews with 6 women and 7 men was performed during May 1999 to January 2000. A follow up focus group interviews with 10 people (2 women and 8 men) was also carried on. The results show that both the Somali culture and Muslim religion do not support the children being taught sex education in schools or the names of the sex organs being pronounced other than to be used as metaphors. The girls, unlike their age group males, experience a very

painful and terrifying process during childhood in which their self-esteem is downgraded by means of serious degrading traditional active violence such as female genital mutilation and visible virginity control. The narratives tell stories in which Somali women are degraded and expected to obey in situations characterised by their man's arbitrariness. They are subject to a very extensive form of social control, which is especially pronounced on issues regarding sexuality. Their integrity as women is, consequently set aside. When Somali refugees came to Sweden some of them came to adopt much of the modern lifestyle and cultural norm systems, preferable young people and some of the females. Relating to a new culture with its new expectations on the norm obedience also created changes in self-esteem. Exile situation tends to generate horizontal conflicts, among spouses and between groups of people. It also tends to generate vertical conflicts because now generations stand up against each other and this is especially pronounced when it is about issues of sexuality and sexual relations. The young generations questions their parents authority. They are now living in new social context and perceive risks, as well as possibilities. Their new dreams and choices, however, do not fit their parents' expectations, which sometimes leads to big problems. From a traditional perspective these deviants lack of respect for traditions and the original culture. From a male perspective this means more specifically a lack of respect for male dominance and superiority.

Adeoye AO. Eye injuries in the young in Ile-Ife, Nigeria. *Niger J Med* 2002; 11(1):26-9. Abstract: One hundred and seventeen children aged 0-17 years treated for eye injuries at the Obafemi Awolowo University Teaching Hospital Ile-Ife, Nigeria were studied. Seventy-five were males and 42 were females with a mean age of 10 years 4 months. Injuries occurred with increasing frequency after the age of 4 years and were commonly sustained by children at play (50.4%); during corporal punishment (10.3%); assault (9.4%) and street hawking (9.4%). Causative agents were mostly sticks and twigs, followed by missiles and fall. Visual prognosis was best in patients with contusion injuries (48.3%) and worst in those with perforating eye injuries (30.5%). Blindness of the injured eye occurred in one-third of the patients and another 17.5% had significant visual impairment. This study shows a variation in the aetiology and visual outcome of eye injuries in the young. Strategies for the prevention of eye injuries are mainly health education, improved supervision of children at play, change in the method of corporal punishment and provision of protective devices for adolescents at work. Early diagnosis and prompt management will improve visual prognosis.

Adib Essali M. Intervention in child abuse and neglect: an emerging subspecialty in child and adolescent

psychiatry. *World Psychiatry* 2005; 4(3):160.

Agatonovic-Kustrin S, Glass BD, Wisch MH, Alany RG. Prediction of a stable microemulsion formulation for the oral delivery of a combination of antitubercular drugs using ANN methodology. *Pharm Res* 2003; 20(11):1760-5.

Abstract: **PURPOSE:** The aim of this project was to develop a colloidal dosage form for the oral delivery of rifampicin and isoniazid in combination with the aid of artificial neural network (ANN) data modeling. **METHODS:** Data from the 20 pseudoternary phase triangles containing miglyol 812 as the oil component and a mixture of surfactants or a surfactant/cosurfactant blend were used to train, test, and validate the ANN model. The weight ratios of individual components were correlated with the observed phase behavior using radial basis function (RBF) network architecture. The criterion for judging the best model was the percentage success of the model prediction. **RESULTS:** The best model successfully predicted the microemulsion region as well as the coarse emulsion region but failed to predict the multiphase liquid crystalline phase for cosurfactant-free systems indicating the difference in microemulsion behavior on dilution with water. **CONCLUSIONS:** A novel microemulsion formulation capable of delivering rifampicin and isoniazid in combination was created to allow for their differences in solubility and potential for chemical reaction. The developed model allowed better understanding of the process of microemulsion formation and stability within pseudoternary colloidal systems.

Agdamag DM, Kageyama S, Alesna ET *et al.* Rapid spread of hepatitis C virus among injecting-drug users in the Philippines: Implications for HIV epidemics. *J Med Virol* 2005; 77(2):221-6.

Abstract: From the trends of human immunodeficiency virus (HIV) epidemics in South and Southeast Asia, it was postulated that an HIV epidemic would start as a blood-borne infection among injecting-drug users in the Philippines. In 2002, 560 individuals were recruited in Metro Cebu, Philippines and tested for HIV, hepatitis C virus (HCV), and hepatitis B virus (HBV) infections. The seroprevalence of anti-HCV among injecting-drug users (70.1%, 61/87) was significantly higher than those among inhalation drug users (16.3%, 7/43;  $P = 0.00$ ; OR = 12), sex workers (0%, 0/130;  $P = 0.00$ ; OR = infinity), antenatal clinic attendees (0%, 0/100;  $P = 0.00$ ; OR = infinity), and students/health care workers (2%, 4/200;  $P = 0.00$ ; OR = 115). The seroprevalence of HBsAg among injecting-drug users (10.3%, 9/87) was significantly higher than those among sex workers (2.3%, 3/130;  $P = 0.01$ ; OR = 4.9), and antenatal clinic attendees (3%, 3/100;  $P = 0.04$ ; OR = 3.7), but was not statistically different from those among inhalation drug users (9.3%, 4/43;  $P = 0.9$ ) and students/health care workers (4.5%, 9/200;  $P = 0.06$ ). None of the study population was reactive to anti-HIV antibody. The HCV strains obtained from the injecting-

drug users belonged to either genotype 1a or 2b and the strains in each genotype clustered closely to each other. There was no dual infection with genotype 1a and 2b. These results suggest that the HCV infection in injecting-drug users may be emanating rapidly from limited number individuals in Metro Cebu, Philippines.

Aghaji MN. Exclusive breast-feeding practice and associated factors in Enugu, Nigeria. *West Afr J Med* 2002; 21(1):66-9.

Abstract: A cross-sectional questionnaire survey was conducted among 235 infant-mother pairs in five Baby Friendly pairs in five Baby Friendly Hospitals in Enugu-Nigeria in 1998. The aims were to study their breast-feeding practices and associated factors. The exclusive breast-feeding rate was 33.3% while the predominant breast-feeding rate was 50.2%. Factors associated with exclusive breast-feeding included infants' birth order ( $P = 0.015$ ), fathers' education ( $P = 0.0244$ ), mothers' education ( $P = 0.000001$ ), occupation ( $P = 0.0069$ ) and parity ( $P = 0.004$ ). However, the infants' age ( $P = 0.054$ ) and sex ( $P = 0.403$ ), mothers' age ( $P = 0.2005$ ), number of breast-feeding counseling attendances ( $P = 0.0883$ ) and the breast-feeding initiator ( $P = 0.473$ ) were comparable irrespective of breast-feeding practice. In the mothers' perspectives, the commonest reasons for not breastfeeding exclusively included; insufficient breast milk (58,37.0%) and the sociocultural practice of giving water to babies because of the hot climate (52,33.1%). For an improvement in the exclusive breast-feeding rate of this population, health workers should highlight to mothers the dangers of water supplementation and the dynamics of breastmilk supply through health education, home visits and the formation of community based lactation support groups.

Aharonson-Daniel L, Waisman Y, Dannon YL, Peleg K. Epidemiology of terror-related versus non-terror-related traumatic injury in children. *Pediatrics* 2003; 112(4):e280.

Notes: CORPORATE NAME: Members of the Israel Trauma Group

Abstract: **OBJECTIVE:** In the past 2 years hundreds of children in Israel have been injured in terrorist attacks. There is a paucity of data on the epidemiology of terror-related trauma in the pediatric population and its effect on the health care system. The objective of this study was to review the accumulated Israeli experience with medical care to young victims of terrorism and to use the knowledge obtained to contribute to the preparedness of medical personnel for future events. **METHODS:** Data on all patients who were younger than 18 years and were hospitalized from October 1, 2000, to December 31, 2001, for injuries sustained in a terrorist attack were obtained from the Israel National Trauma Registry. The parameters evaluated were patient age and sex, diagnosis, type, mechanism and severity of injury, interhospital transfer, stay in

intensive care unit, duration of hospitalization, and need for rehabilitation. Findings were compared with the general pediatric population hospitalized for non-terror-related trauma within the same time period. **RESULTS:** During the study period, 138 children were hospitalized for a terror-related injury and 8363 for a non-terror-related injury. The study group was significantly older (mean age: 12.3 years [standard deviation: 5.1] v 6.9 years [standard deviation: 5.3]) and sustained proportionately more penetrating injuries (54% [n = 74] vs 9% [n = 725]). Differences were also noted in the proportion of internal injuries to the torso (11% in the patients with terror-related trauma vs 4% in those with non-terror-related injuries), open wounds to the head (13% vs 6%), and critical injuries (Injury Severity Score of 25+; 25% vs 3%). The study group showed greater use of intensive care unit facilities (33% vs 8% in the comparison group), longer median hospitalization time (5 days vs 2 days), and greater need for rehabilitative care (17% vs 1%). **CONCLUSIONS:** Terror-related injuries are more severe than non-terror-related injuries and increase the demand for acute care in children.

Ahmad Z, Balsamo LM, Sachs BC, Xu B, Gaillard WD. Auditory comprehension of language in young children: neural networks identified with fMRI. *Neurology* 2003; 60(10):1598-605. Abstract: **OBJECTIVE:** The organization of neuronal systems that process language in young children is poorly understood. The authors used fMRI to identify brain regions underlying auditory comprehension in healthy young children. **METHODS:** Fifteen right-handed children (mean age 6.8 years) underwent fMRI at 1.5-T using blood oxygen level dependent echoplanar imaging. They listened to stories with a reverse speech control condition. Group data were analyzed with statistical parametric mapping. Individual subject data were analyzed with a region of interest approach based on t-maps. An asymmetry index ( $AI = [(L-R)/(L+R)]$ ) was calculated for each region. **RESULTS:** Group analysis showed significant activation in the left middle temporal gyrus (Brodmann area [BA] 21) and left superior temporal gyrus (BA 22) along the superior temporal sulcus extending back to the angular gyrus (BA 39). Individual maps showed lateralized activation in temporal regions ( $AI > 0.49 \pm 0.39$ ). There was minimal activation in the frontal lobe. There were no significant correlations between age and regional AI. **CONCLUSION:** Networks for auditory language processing are regionally localized and lateralized by age 5. These data may provide a means to interpret language fMRI studies performed in preparation for brain surgery, and may be employed to investigate the effect of chronic disease states, such as epilepsy, on language organization during critical periods for plasticity.

Ahmed AU, O'Halloran SM, Roland NJ, Starkey M, Wraith JE. Hearing loss due to mannosidosis and otitis

media with effusion. A case report and review of audiological assessments in children with otitis media with effusion. *J Laryngol Otol* 2003; 117(4):307-9. Abstract: A case of a child with mannosidosis and bilateral otitis media with effusion (OME) is reported here along with some discussion of relevant literature to emphasize the need for age appropriate audiometric assessment before and after insertion of grommets for glue ear (OME). There is a need for multidisciplinary teamwork in the management of children with hearing loss. If OME is treated surgically, age-appropriate hearing assessment is required before and after insertion of grommets. The need for audiological assessments will be relevant even if children had passed the newborn hearing screening test.

Aitken ME, Rowlands LA, Wheeler JG. Advocating for children's health at the state level: lessons learned. *Arch Pediatr Adolesc Med* 2001; 155(8):877-80. Abstract: This article documents the successful creation and promotion of a bill to fund a nurse home visitation program for high-risk mothers in Arkansas. It illustrates several key factors in successful advocacy by pediatricians working in an academic setting: a realistic time commitment; a community needs assessment, data assimilation, and review of existing resources; the identification and incorporation of stakeholders; a narrow focus on the area of greatest need; the backing of political partners; and favorable opportunities to advance child health issues.

Ajrouch KJ, Antonucci TC, Janevic MR. Social networks among blacks and whites: the interaction between race and age. *J Gerontol B Psychol Sci Soc Sci* 2001; 56(2):S112-8. Abstract: **OBJECTIVES:** This study examined the main and interactive effects of age and race on the core characteristics of social networks including size, frequency of contact, geographical proximity, and composition of network. **METHODS:** Respondents were drawn from a stratified probability sample of people aged 20-93 in the greater Detroit metropolitan area. Approximately 30% of the sample were African American, and people aged 60 and older were over-sampled (n = 1,382). The authors used hierarchical regression analysis to estimate the influence of race and age on each component of social network, controlling for marital status, gender, and education. An interaction term (Race x Age) was added to explore the extent to which age moderates any detected race differences. **RESULTS:** Older age was associated with smaller, less frequently seen, and less proximal networks that had a higher proportion of kin. Blacks and Whites were similar with regard to proximity, but Blacks had smaller networks, more contact with network members, and more family members in their networks. Race differences in frequency of contact and proportion of kin were moderated by age, such that the differences in these variables diminished with increasing age. **DISCUSSION:** A systematic analysis

of how age, race, and their interaction influence the characteristics of social networks furnishes important empirical knowledge about social networks among diverse groups. Such data may provide a context for how, and some explanation for why, support exchanges occur.

Akid M. Child protection. Baseline training is not enough. *Nurs Times* 2002; 98(7):8.

Akister J, Johnson K. Parenting issues that may be addressed through a confidential helpline. *Health Soc Care Community* 2002; 10(2):106-11. Abstract: This study identifies what parents might expect from a confidential helpline and highlights areas of parental concern in the task of child-rearing. A community sample of 424 families from four schools was collected. Although many issues raised concerned parents, those particularly cited were behaviour management, school bullying and drug and alcohol problems. It is clear that there is a perceived need by parents for input into the parenting process; parents were seeking information and advice rather than support. The question of which aspects of parenting can be developed, either through a helpline or other services, is discussed.

Akpede GO, Lawal RS, Momoh SO. Perception of voluntary screening for paediatric HIV and response to post-test counselling by Nigerian parents. *AIDS Care* 2002; 14(5):683-97.

Abstract: Nigeria may be taken to represent countries with an evolving HIV/AIDS epidemic. With particular reference to paediatric HIV, the voluntary testing of young children and their parents may provide an important entry point for the institution of control measures. However, there is a paucity of knowledge about how individuals perceive voluntary testing. This knowledge is important to the development of guidelines for counselling. To reduce this gap, 258 parents of hospitalized children (> 1 month to 15 years of age) were interviewed using a structured questionnaire. In addition, to complement the data, four examples of seropositive mother's responses during post-test counselling are presented and analyzed. In the survey, 223 (86%) parents were HIV/AIDS aware but only 88 (39%) of these parents could describe one or more route(s) of transmission and none described vertical transmission. Among the respondents, 153 (62%) of 248 would consent to the screening of self, and 195 (85%) of 230 to the screening of a hospitalized child if based on his/her clinical condition. Perceptions of good health and lack of exposure, and despair owing to lack of a specific treatment, were the common reasons for refusing consent. These represent some of the issues which would need to be addressed to increase the acceptance of voluntary testing. The fear of a break up of families with seropositive mothers but seronegative fathers was a major concern expressed

during post-test counselling. HIV-discordance among couples may be frequent and should be considered in the formulation of policies on counselling and voluntary testing.

Akshoomoff NA, Feroletto CC, Doyle RE, Stiles J. The impact of early unilateral brain injury on perceptual organization and visual memory. *Neuropsychologia* 2002; 40(5):539-61.

Abstract: Studies of young children with early unilateral brain injury have suggested that while hemispheric differences in visuospatial processing appear to be present early in development, the young brain is better able to compensate for injury than when the injury occurs later, after networks have been established. The aim of this study was to determine if this pattern continues later in development when these children are given a challenging task: the Rey-Osterrieth Complex Figure. Experiment 1 included longitudinal data from ten children with early left hemisphere (LH) injury and nine children with early right hemisphere (RH) injury. Injury was presumed to be due to a prenatal or perinatal stroke. Compared with typically developing children, both groups were poorer in copying the figure. With development, these children produced reasonably accurate drawings but continued to use the most immature and piecemeal strategy. In Experiment 2, copy and immediate memory drawings from the 19 children with early unilateral brain injury were collected at a single age (11-14 years). Eight of the ten children with LH injury organized their memory reproductions around the core rectangle but included relatively few additional details. In contrast, only two of the nine children with RH injury organized their memory reproductions around the core rectangle and all but one produced the figure in a piecemeal manner. The results from both studies demonstrate the continuation of subtle deficits in visuospatial analysis with development but also the continued capacity for compensation.

Alati R, Najman JM, Kinner SA *et al.* Early predictors of adult drinking: a birth cohort study. *Am J Epidemiol* 2005; 162(11):1098-107.

Abstract: Few studies have explored early predictors of problem drinking in youth, and fewer still have simultaneously considered the role of biologic, familial, and intrapersonal factors. The present study explored early life course and later life course predictors of alcohol abuse and dependence in young adulthood. Data were taken from a cohort of 2,551

mothers and their children recruited as part of the longitudinal Mater University Study of Pregnancy and its outcomes (MUSP) carried out in Brisbane, Australia, from 1981 to 1984. Data were collected prenatally and then postnatally at 6 months and at 5, 14, and 21 years. A range of biologic, familial, and intrapersonal factors was considered. A series of logistic regression models with inverse probability weighting was used to explore pathways to problem drinking from adolescence to early adulthood. For males and females, no association was found between either birth factors or childhood factors and a lifetime diagnosis of alcohol disorders at age 21 years. Externalizing symptoms and maternal factors at age 14 years were significantly associated with alcohol problems. For youth aged 14 years, maternal moderate alcohol consumption accounted for the highest percentage of attributable risk among those exposed. Results show that exposure to maternal drinking in adolescence is a strong risk factor for the development of alcohol problems in early adulthood.

Alber TS. [Chlamydia trachomatis and Neisseria gonorrhoeae in sexually abused children in Jutland]. *Ugeskr Laeger* 2003; 165(5):481; author reply 481.

Albertyn R, Bickler SW, van As AB, Millar AJ, Rode H. The effects of war on children in Africa. *Pediatr Surg Int* 2003; 19(4):227-32. Abstract: There is no doubt that the effects of war extend to the most vulnerable members of society, including children. Although armed conflicts occur throughout the world, the African continent seems to be a particular background for civil and international wars. The aim of this study was to identify causes of conflict in Africa and to evaluate the effect of war on children and their health in order to make practical recommendations to health care workers dealing with children in the setting of war. All articles written in the past 5 years concerning "war" and "children" were identified by means of a literature search and internet review. Contrary to common belief, the causes of conflict are complicated and multi-factorial. The effects of war on childhood are disastrous and include severe negative effects on general paediatric health status. Short-term recommendations for health care workers working with children in war include supply of emergency medical infrastructures, basic health care, rehabilitation and education. Long-term recommendations include orchestrating the relief and support efforts from both national governments and international non-profit organisations and speeding up of economic recovery. The causes of conflict in Africa are complex and unlikely to be resolved soon. The effects of war on children are horrendous in many ways, but can be limited by providing timely and appropriate health care.

Albrecht A, Vinterbo SA, Ohno-Machado L. An Epicurean

learning approach to gene-expression data classification. *Artif Intell Med* 2003; 28(1):75-87. Abstract: We investigate the use of perceptrons for classification of microarray data where we use two datasets that were published in [Nat. Med. 7 (6) (2001) 673] and [Science 286 (1999) 531]. The classification problem studied by Khan et al. is related to the diagnosis of small round blue cell tumours (SRBCT) of childhood which are difficult to classify both clinically and via routine histology. Golub et al. study acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL). We used a simulated annealing-based method in learning a system of perceptrons, each obtained by resampling of the training set. Our results are comparable to those of Khan et al. and Golub et al., indicating that there is a role for perceptrons in the classification of tumours based on gene-expression data. We also show that it is critical to perform feature selection in this type of models, i.e. we propose a method for identifying genes that might be significant for the particular tumour types. For SRBCTs, zero error on test data has been obtained for only 13 out of 2308 genes; for the ALL/AML problem, we have zero error for 9 out of 7129 genes that are used for the classification procedure. Furthermore, we provide evidence that Epicurean-style learning and simulated annealing-based search are both essential for obtaining the best classification results.

Albrecht SA, Maloni JA, Thomas KK, Jones R, Halleran J, Osborne J. Smoking cessation counseling for pregnant women who smoke: scientific basis for practice for AWHONN's SUCCESS project. *J Obstet Gynecol Neonatal Nurs* 2004; 33(3):298-305. Abstract: OBJECTIVES: To review the literature addressing smoking cessation in pregnant women. To develop the project protocol for the Association of Women's Health, Obstetric and Neonatal Nurse's (AWHONN) 6th research-based practice project titled "Setting Universal Cessation Counseling, Education and Screening Standards (SUCCESS): Nursing Care of Pregnant Women Who Smoke." To evaluate the potential of systematic integration of this protocol in primary care settings in which women seek care at the preconception, pregnant, or postpartum stages. LITERATURE SOURCES: Computerized searches in MEDLINE and CINAHL, as well as references cited in articles reviewed. Key concepts in the searches included low-birth-weight infants and effects of prenatal smoking on the infant and the effects of preconception and prenatal smoking cessation intervention on premature labor and birth weight. LITERATURE SELECTION: Comprehensive articles, reports, and guidelines relevant to key concepts and published after 1964 with an emphasis on new findings from 1996 through 2002. Ninety-eight citations were identified as useful to this review. LITERATURE SYNTHESIS: Tobacco use among pregnant women and children's exposure to tobacco use (secondhand smoke) are associated with pregnancy complications

such as placental dysfunction (including previa or abruption), preterm labor, premature rupture of membranes, spontaneous abortions, and decreased birth weight and infant stature. Neonates and children who are exposed to secondhand smoke are at increased risk for developing otitis media, asthma, other respiratory disorders later in childhood; dying from sudden infant death syndrome; and learning disorders. The "5 A's" intervention and use of descriptive statements for smoking status assessment were synthesized into the SUCCESS project protocol for AWHONN's 6th research-based practice project. CONCLUSIONS: The literature review generated evidence that brief, office-based assessment, client-specific tobacco counseling, skill development, and support programs serve as an effective practice guideline for clinicians. Implementation and evaluation of the guideline is under way at a total of 13 sites in the United States and Canada.

Albright TA, Binns HJ, Katz BZ. Side effects of and compliance with malaria prophylaxis in children. *J Travel Med* 2002; 9(6):289-92. Abstract: BACKGROUND: We wanted to determine the frequency of side effects and compliance with mefloquine and chloroquine used for antimalarial prophylaxis in children 0 to 13 years compared with side effects in same-age children taking prophylactic chloroquine. METHODS: Subjects and treatment were identified by retrospective medical record review for children < or = 13 years not on other medications who visited a travel clinic between November 1997 and January 2000. Parents were interviewed via telephone in January through March 2000 regarding compliance and side effects. RESULTS: We reviewed 286 records and contacted 190 of 286 parents (66%). Of these, 177 (93%) parents had first-hand knowledge about the child's compliance with the medication regimen and were interviewed. Subjects were 47% male (median age 6.3 years), contacted a median of 12.4 months (range 2.8 to 28 months) following their clinic visit. Of these, 148 (84%) were prescribed mefloquine, and 29, chloroquine with 77% (136/177) taking the prescribed antimalarial. Most children (30 of 41 [73%]) not receiving their prophylaxis traveled unprotected to endemic area. Sixteen subjects (12% of those taking antimalarials) reported side effects. Eleven of 115 subjects (10%) who took mefloquine, and 5 of 22 subjects (23%) who took chloroquine reported a side effect. Side effects for mefloquine included diarrhea, anorexia, vivid dreams, headache, changes in sleep, hallucinations, and vomiting with 2 subjects stopping mefloquine after seeking medical care. Side effects for chloroquine were headache, nausea, and changes in sleep. No child stopped taking chloroquine. Groups reporting or not reporting a side effect were similar for gender, age, travel destination, antimalarial prescribed, and elapsed time from clinic visit to telephone contact. CONCLUSIONS: Side effects from antimalarial drug administration occurred in 10 to 23% of patients who

took their medication but rarely resulted in stopping prophylaxis. Prescribed antimalarials were sometimes never given. Appropriate counseling on side effects and reasons for faithful administration should accompany antimalarial prophylaxis.

Alechnowicz K, Chapman S. The Philippine tobacco industry: "the strongest tobacco lobby in Asia". *Tob Control* 2004; 13 Suppl 2:ii71-8. Abstract: OBJECTIVE: To highlight revelations from internal tobacco industry documents about the conduct of the industry in the Philippines since the 1960s. Areas explored include political corruption, health, employment of consultants, resisting pack labelling, and marketing and advertising. METHODS: Systematic keyword Minnesota depository website searches of tobacco industry internal documents made available through the Master Settlement Agreement. RESULTS: The Philippines has long suffered a reputation for political corruption where collusion between state and business was based on the exchange of political donations for favourable economic policies. The tobacco industry was able to limit the effectiveness of proposed anti-tobacco legislation. A prominent scientist publicly repudiated links between active and passive smoking and disease. The placement of health warning labels was negotiated to benefit the industry, and the commercial environment allowed it to capitalise on their marketing freedoms to the fullest potential. Women, children, youth, and the poor have been targeted. CONCLUSION: The politically laissez faire Philippines presented tobacco companies with an environment ripe for exploitation. The Philippines has seen some of the world's most extreme and controversial forms of tobacco promotion flourish. Against international standards of progress, the Philippines is among the world's slowest nations to take tobacco control seriously.

Alemi F, Haack M, Nemes S. Statistical definition of relapse: case of family drug court. *Addict Behav* 2004; 29(4):685-98.

Abstract: At any point in time, a patient's return to drug use can be seen either as a temporary event or as a return to persistent use. There is no formal standard for distinguishing persistent drug use from an occasional relapse. This lack of standardization persists although the consequences of either interpretation can be life altering. In a drug court or regulatory situation, for example, misinterpreting relapse as return to drug use could lead to incarceration, loss of child custody, or loss of employment. A clinician who mistakes a client's relapse for persistent drug use may fail to adjust treatment intensity to client's needs. An empirical and standardized method for distinguishing relapse from persistent drug use is needed. This paper provides a tool for clinicians and judges to distinguish relapse from persistent use based on statistical analyses of patterns of client's drug use. To accomplish this, a control chart is created for time-in-between relapses.

This paper shows how a statistical limit can be calculated by examining either the client's history or other clients in the same program. If client's time-in-between relapse exceeds the statistical limit, then the client has returned to persistent use. Otherwise, the drug use is temporary. To illustrate the method, it is applied to data from three family drug courts. The approach allows the estimation of control limits based on the client's as well as the court's historical patterns. The approach also allows comparison of courts based on recovery rates.

Alfredsson R, Svensson E, Trollfors B, Borres MP. Why do parents hesitate to vaccinate their children against measles, mumps and rubella? *Acta Paediatr* 2004; 93(9):1232-7.

Abstract: **BACKGROUND:** Thanks to a successful voluntary vaccination programme, measles, mumps and rubella are rare diseases in Sweden. Coverage among children 18 mo of age has been 99%, but the measles, mumps and rubella vaccination (MMR) has increasingly been questioned among parents. **AIM:** To study reasons why parents choose not to vaccinate their child against measles, mumps and rubella, and their opinions on vaccines and the diseases themselves. A secondary objective was to compare coverage at 18 mo of age based on parental report with the national statistics based on patient charts. **METHODS:** The official statistics were compared with patient charts for two birth cohorts in the city of Goteborg, Sweden. Out of these children born in 1995 and 1996, 300 unvaccinated and vaccinated children were identified. Their parents received a postal questionnaire assessing the parent's views on vaccines and childhood diseases. **RESULTS:** The documented vaccine coverage in this study was higher in 1995 and 1996 than official statistics indicated. The major reason, for both groups, for accepting respectively declining vaccination was strengthening the child's immune system. Parents with children unvaccinated against MMR were also more likely to have declined vaccination against diphtheria, polio, tetanus, *Haemophilus influenzae* and pertussis. One-third of the parents with a child unvaccinated against MMR had not yet made their final decision 3 y after the vaccine offer. Few parents, both with vaccinated and unvaccinated children, had acquired vaccine information from the Internet. Both groups believed that insufficient time was allocated for vaccine information and discussion at the Child Health Centre. **CONCLUSION:** Our study indicates that official statistics on MMR vaccination uptake

underestimate the number of vaccinated children. Vaccine safety is a major concern for many parents and needs to be addressed by healthcare professionals at institutions offering paediatric vaccinations.

Alidina S, Jarvis S, Nickoloff B, Tolkin J, Trypuc J. Connecting for change: networks as a vehicle for regional health reform the early experiences of the Child Health Network for the Greater Toronto Area. *Healthc Manage Forum* 2002; 15(2):41-5. Abstract: The Child Health Network (CHN) for the Greater Toronto Area (GTA) is a partnership of hospital, rehabilitation and community providers committed to developing a regional system to deliver high quality, accessible, family-centred care for mothers, newborns, children and youth. This article reviews the history and model of the CHN, assesses its achievements, and provides insights into the challenges and lessons learned by the network. Stemming from the CHN's commitment to quality, accessibility and efficiency, regionalization of maternal, newborn and children's services is emerging as a success story.

Alkan N, Baksu A, Baksu B, Goker N. Gynecological examinations for social and legal reasons in Turkey: hospital data. *Croat Med J* 2002; 43(3):338-41. Abstract: **AIM:** Women in Turkey are subjected to gynecologic examinations not only for legal reasons, such as sexual assault or violence against pregnant women, but also for various social reasons, such as suspicions of premarital intercourse, prostitution, loss of virginity, and pregnancy at the time of entering into a new marriage. The examinations are performed by general practitioners, forensic physicians, and gynecologists. This study presents social reasons for gynecologic examinations of women in Turkey. **METHOD:** We analyzed the reasons for gynecologic examination of 412 women at the 1st Obstetrics and Gynecology Department, Sisli Etfal Training and Research Hospital, between January 1, 1999 and June 30, 2001. **RESULTS:** Out of 27,376 women at the Department, 412 (1.5%) underwent gynecologic examination for social or legal reasons: 82 (19.9%) for entering into a new marriage, 41 (10.1%) for violence against pregnant women, 28 (6.7%) for sexual assault, 53 (12.8%) for suspicion of prostitution, and 208 (50.5%) for the determination of virginity. **CONCLUSION:** Gynecologic examinations for legal or social reasons in Turkey are still rather common. Medicolegal regulation of gynecological examinations should be changed to protect women's human rights.

Allasio D, Fischer H. Re: Shaken baby syndrome and hypothermia. *Child Abuse Negl* 2001; 25(11):1413-4.

Allmark P, Mason S, Gill AB, Megone C. Is it in a neonate's best interest to enter a randomised controlled trial? *J Med Ethics* 2001; 27(2):110-3. Notes: **GENERAL NOTE:** KIE: Allmark, Peter;

Mason, Su; Gill, A Bryan; Megone, Christopher  
GENERAL NOTE: KIE: 20 refs.  
GENERAL NOTE: KIE: KIE Bib: human experimentation/minors

Abstract: Clinicians are required to act in the best interest of neonates. However, it is not obvious that entry into a randomised controlled trial (RCT) is in a neonate's best interest because such trials often involve additional onerous procedures (such as intramuscular injections) in return for which the neonate receives unproven treatment or a placebo. On the other hand, neonatology needs to develop its evidence base, and RCTs are central to this task. The solution posited here is based on two points. First, "best interest" is not equivalent to "the best possible interest" only to "best interest within a certain realm". The realm of deliberation when asking the title question is the neonate's health. Deliberating in this realm may involve the exclusion from consideration of some factors that might be thought relevant (such as parental wealth). Furthermore, circumstances may dictate the need to deliberate on other factors that might be thought irrelevant (such as health care resources). Second, deciding on a neonate's best interest does not involve "putting oneself in its shoes". Rather, it involves asking in what it has an interest, or stake. These will include some things in which we all, as human beings, have a stake, such as medical progress. Putting these two points together, in the realm of health the answer to whether RCT entry is in a neonate's best interest is usually very finely balanced. Where this is the case, it is reasonable to invoke a broader notion of best interest and include a broader range of elements in which the neonate has a stake, including medical progress. In this way RCT entry can, usually, be said to be in a neonate's best interest.

Allsworth JE, Zierler S, Lapane KL, Krieger N, Hogan JW, Harlow BL. Longitudinal study of the inception of perimenopause in relation to lifetime history of sexual or physical violence. *J Epidemiol Community Health* 2004; 58(11):938-43.

Abstract: **STUDY OBJECTIVE:** To investigate of the extent to which violence over the life course accelerates the onset of perimenopause, as measured by menstrual changes. **DESIGN:** Prospective cohort study. **SETTING:** Boston, Massachusetts. **PARTICIPANTS:** 603 premenopausal women aged 36-45 years at baseline who completed a cross sectional survey on childhood and adult violence history. **MAIN OUTCOME MEASURE:** Time to perimenopause, defined as time in months from baseline interview to a woman's report of (1) an absolute change of at least seven days in menstrual cycle length from baseline or subjective report of menstrual irregularity; (2) a change in menstrual flow amount or duration; or (3) cessation of periods for at least three months, whichever came first. **MAIN RESULTS:** Experience of abuse was associated with delayed onset of menstrual changes indicative of onset of perimenopause. Women

reporting childhood or adolescent abuse entered perimenopause about 35% slower than women who reported no abuse (IRR(adj) = 0.65, 95% CI 0.45 to 0.95) after adjusting for age, age at menarche, ever live birth, ability to maintain living standard, smoking, BMI, and depression. There was a similar association among women who reported first abuse during adulthood (IRR(adj) = 0.72, 95% CI 0.28 to 1.80). These findings persisted when the cohort was restricted to non-depressed women (childhood/adolescent IRR(adj) = 0.57, 95% CI 0.36 to 0.90; adulthood IRR(adj) = 0.63, 95% CI 0.23 to 1.77). **CONCLUSIONS:** This study is the first longitudinal analysis of the timing of perimenopause to show an association with a history of physical or sexual abuse. Further study of the relation between violence and reproductive aging is needed.

Almogly G, Luria T, Richter E *et al.* Can external signs of trauma guide management?: Lessons learned from suicide bombing attacks in Israel. *Arch Surg* 2005; 140(4):390-3.

Abstract: **BACKGROUND:** Following a suicide bombing attack, scores of victims suffering from a combination of blast injury, penetrating injury, and burns are brought to local hospitals. **OBJECTIVE:** To identify external signs of trauma that would assist medical crews in recognizing blast lung injury (BLI) and effectively triaging salvageable and nonsalvageable victims. **DESIGN:** Retrospective analysis of all 15 suicide bombing attacks that occurred in Israel from April 1994 to August 1997. **SETTING:** National survey. **PATIENTS:** One hundred fifty-three victims died and 798 were injured as a result of 15 attacks. Medical records were reviewed for external signs of trauma, such as burns and penetrating injuries, and the presence of BLI. **Main Outcome Measure** The odds ratio for BLI and death. **RESULTS:** Three settings were targeted: buses, semiconfined spaces, and open spaces. Sixty survivors (7.5%) suffered from BLI, which was more common in buses (37 of 260) than semiconfined spaces (14 of 279) and open spaces (9 of 259) (P<.001). Victims with BLI were more likely to suffer from penetrating injury to the head or torso, burns covering more than 10% of the body surface area, and skull fractures (odds ratios, 4, 11.6, and 55.8, respectively; P<.001). Victims who died at the scene were more likely to suffer from burns, open fractures, and amputations in comparison with survivors (odds ratios, 6.5, 18.6, and 50.1, respectively; P<.001). **CONCLUSIONS:** Following a suicide bombing attack, external signs of trauma should be used to triage victims to the appropriate level of care both at the scene and in the hospital. Triage of salvageable and nonsalvageable victims should take into account the presence of amputations, burns, and open fractures.

Alter MJ. Do patients who fail to complete a hepatitis A or hepatitis B vaccination series have to restart it? *Cleve Clin J Med* 2003; 70(3):234.

Altshuler SJ. Drug-endangered children need a collaborative community response. *Child Welfare* 2005; 84(2):171-90.

Abstract: The United States is facing an epidemic of the use of methamphetamine drugs. Child welfare has not yet addressed the needs of the children living in so-called "meth homes." These children are endangered not only from the chemicals involved, but also from parental abuse and neglect. Communities are recognizing the need for interagency collaboration to address the consequences of this epidemic. Spokane, Washington, has created a Drug-Endangered Children Project, whose mission is to implement a collaborative response among law enforcement, prosecutorial, medical, and social service professionals to the needs of drug-endangered children. This article presents the findings from the evaluation of the first year of the project, including a baseline assessment of the needs of drug-endangered children and the extent of community-based collaboration achieved. This article makes recommendations for future community-based partnerships to improve the well-being of drug-endangered children.

Alvarado BE, Zunzunegui MV, Delisle H. [Validation of food security and social support scales in an Afro-Colombian community: application on a prevalence study of nutritional status in children aged 6 to 18 months]. *Cad Saude Publica* 2005; 21(3):724-36. Abstract: We conducted a cross-sectional study on 193 mothers of children 6 to 18 months of age in an African-Colombian community, with the objectives: (1) to adapt and validate the Community Childhood Hunger Identification Project scale, the DUKE-UNC-11 social support scale, and the Quebec Longitudinal Study of Child Development (QLSCD) partner support scale, and (2) to identify any existent relationship between nutritional status in infancy and both food insecurity and social support. We determined construct validity using factor analysis and theoretical models-based non-parametric correlations. Length-for-age and weight-for-length Z-results were calculated. Factor analyses reduced the hunger scale to one factor, the DUKE-UNC-11 scale to two factors, and the QLSCD scale to one factor. The Cronbach's alpha test ranged between 0.70 and 0.90. Both food insecurity and social support scales were correlated with mother's social conditions, and social support was positively associated with social networks and mother's self-perceived health status. Food insecurity, emotional-social support, and partner's negative support were associated with lower height-to-age and therefore a higher ratio of chronic malnutrition. The study supports the appropriateness of the instruments to measure the expressed concepts.

Aman MG, De Smedt G, Derivan A, Lyons B, Findling RL. Double-blind, placebo-controlled study of risperidone for the treatment of disruptive behaviors in children with subaverage intelligence. *Am J Psychiatry* 2002; 159(8):1337-46.

Notes: CORPORATE NAME: Risperidone Disruptive Behavior Study Group

Abstract: OBJECTIVE: The short-term efficacy and safety of risperidone in the treatment of disruptive behaviors was examined in a well-characterized cohort of children with subaverage intelligence. METHOD: In this 6-week, multicenter, double-blind, parallel-group study of 118 children (aged 5-12 years) with severely disruptive behaviors and subaverage intelligence (IQ between 36 and 84, inclusive), the subjects received 0.02-0.06 mg/kg per day of risperidone oral solution or placebo. The a priori primary efficacy measure was the change in score from baseline to endpoint on the conduct problem subscale of the Nisonger Child Behavior Rating Form. RESULTS: The risperidone group showed significantly greater improvement than did the placebo group on the conduct problem subscale of the Nisonger Child Behavior Rating Form from week 1 through endpoint (change in score of -15.2 and -6.2, respectively). Risperidone was also associated with significantly greater improvement than placebo on all other Nisonger Child Behavior Rating Form subscales at endpoint, as well as on the Aberrant Behavior Checklist subscales for irritability, lethargy/social withdrawal, and hyperactivity; the Behavior Problems Inventory aggressive/destructive behavior subscale; a visual analogue scale of the most troublesome symptom; and the Clinical Global Impression change score. The most common adverse effects reported during risperidone treatment were headache and somnolence. The extrapyramidal symptom profile of risperidone was comparable to that of placebo. Mean weight increases of 2.2 kg. and 0.9 kg occurred in the risperidone and placebo groups, respectively. CONCLUSIONS: Risperidone was effective and well tolerated for the treatment of severely disruptive behaviors in children with subaverage IQ.

Ambalavanan N, Carlo WA. Comparison of the prediction of extremely low birth weight neonatal mortality by regression analysis and by neural networks. *Early Hum Dev* 2001; 65(2):123-37.

Abstract: AIMS: To compare the prediction of mortality in individual extremely low birth weight (ELBW) neonates by regression analysis and by artificial neural networks. STUDY DESIGN: A database of 23 variables on 810 ELBW neonates admitted to a tertiary care center was divided into training, validation, and test sets. Logistic regression and neural network models were developed on the training set, validated, and outcome (mortality) predicted on the test set. Stepwise regression identified significant variables in the full set. Regression models and neural networks were then tested using data sets

with only the identified significant variables, and then with variables excluded one at a time. RESULTS: The area under the curve (AUC) of receiver operating characteristic (ROC) curves for neural networks and regression was similar (AUC 0.87+/-0.03; p=0.31). Birthweight or gestational age and the 5-min Apgar score contributed most to AUC. CONCLUSIONS: Both neural networks and regression analysis predicted mortality with reasonable accuracy. For both models, analyzing selected variables was superior to full data set analysis. We speculate neural networks may not be superior to regression when no clear non-linear relationships exist.

Ambalavanan N, Carlo WA, Bobashev G *et al.* Prediction of death for extremely low birth weight neonates. *Pediatrics* 2005; 116(6):1367-73. Notes: CORPORATE NAME: National Institute of Child Health and Human Development Neonatal Research Network Abstract: OBJECTIVE: To compare multiple logistic regression and neural network models in predicting death for extremely low birth weight neonates at 5 time points with cumulative data sets, as follows: scenario A, limited prenatal data; scenario B, scenario A plus additional prenatal data; scenario C, scenario B plus data from the first 5 minutes after birth; scenario D, scenario C plus data from the first 24 hours after birth; scenario E, scenario D plus data from the first 1 week after birth. METHODS: Data for all infants with birth weights of 401 to 1000 g who were born between January 1998 and April 2003 in 19 National Institute of Child Health and Human Development Neonatal Research Network centers were used (n = 8608). Twenty-eight variables were selected for analysis (3 for scenario A, 15 for scenario B, 20 for scenario C, 25 for scenario D, and 28 for scenario E) from those collected routinely. Data sets censored for prior death or missing data were created for each scenario and divided randomly into training (70%) and test (30%) data sets. Logistic regression and neural network models for predicting subsequent death were created with training data sets and evaluated with test data sets. The predictive abilities of the models were evaluated with the area under the curve of the receiver operating characteristic curves. RESULTS: The data sets for scenarios A, B, and C were similar, and prediction was best with scenario C (area under the curve: 0.85 for regression; 0.84 for neural networks), compared with scenarios A and B. The logistic regression and neural network models performed similarly well for scenarios A, B, D, and E, but the regression model was superior for scenario C. CONCLUSIONS: Prediction of death is limited even with sophisticated statistical methods such as logistic regression and nonlinear modeling techniques such as neural networks. The difficulty of predicting death should be acknowledged in discussions with families and caregivers about decisions regarding initiation or continuation of care.

Anagol P. The emergence of the female criminal in India: infanticide and survival under the Raj. *Hist Workshop J* 2002; (53):73-93.

Anda RF, Whitfield CL, Felitti VJ *et al.* Adverse childhood experiences, alcoholic parents, and later risk of alcoholism and depression. *Psychiatr Serv* 2002; 53(8):1001-9.

Abstract: OBJECTIVE: The study examined how growing up with alcoholic parents and having adverse childhood experiences are related to the risk of alcoholism and depression in adulthood. METHODS: In this retrospective cohort study, 9,346 adults who visited a primary care clinic of a large health maintenance organization completed a survey about nine adverse childhood experiences: experiencing childhood emotional, physical, and sexual abuse; witnessing domestic violence; parental separation or divorce; and growing up with drug-abusing, mentally ill, suicidal, or criminal household members. The associations between parental alcohol abuse, the adverse experiences, and alcoholism and depression in adulthood were assessed by logistic regression analyses. RESULTS: The risk of having had all nine of the adverse childhood experiences was significantly greater among the 20 percent of respondents who reported parental alcohol abuse. The number of adverse experiences had a graded relationship to alcoholism and depression in adulthood, independent of parental alcohol abuse. The prevalence of alcoholism was higher among persons who reported parental alcohol abuse, no matter how many adverse experiences they reported. The association between parental alcohol abuse and depression was accounted for by the higher risk of having adverse childhood experiences in alcoholic families. CONCLUSIONS: Children in alcoholic households are more likely to have adverse experiences. The risk of alcoholism and depression in adulthood increases as the number of reported adverse experiences increases regardless of parental alcohol abuse. Depression among adult children of alcoholics appears to be largely, if not solely, due to the greater likelihood of having had adverse childhood experiences in a home with alcohol-abusing parents.

Anderson M, Kaufman J, Simon TR *et al.* School-associated violent deaths in the United States, 1994-1999. *JAMA* 2001; 286(21):2695-702.

Notes: CORPORATE NAME: School-Associated Violent Deaths Study Group Abstract: CONTEXT: Despite the public alarm following a series of high-profile school shootings that occurred in the United States during the late 1990s, little is known about the actual incidence and characteristics of school-associated violent deaths. OBJECTIVE: To describe recent trends and features of school-associated violent deaths in the United States. DESIGN, SETTING, AND SUBJECTS: Population-based surveillance study of data collected from media databases, state and local agencies, and police and

school officials for July 1, 1994, through June 30, 1999. A case was defined as a homicide, suicide, legal intervention, or unintentional firearm-related death of a student or nonstudent in which the fatal injury occurred (1) on the campus of a public or private elementary or secondary school, (2) while the victim was on the way to or from such a school, or (3) while the victim was attending or traveling to or from an official school-sponsored event. MAIN OUTCOME MEASURES: National estimates of risk of school-associated violent death; national trends in school-associated violent deaths; common features of these events; and potential risk factors for perpetration and victimization. RESULTS: Between 1994 and 1999, 220 events resulting in 253 deaths were identified; 202 events involved 1 death and 18 involved multiple deaths (median, 2 deaths per multiple-victim event). Of the 220 events, 172 were homicides, 30 were suicides, 11 were homicide-suicides, 5 were legal intervention deaths, and 2 were unintentional firearm-related deaths. Students accounted for 172 (68.0%) of these deaths, resulting in an estimated average annual incidence of 0.068 per 100 000 students. Between 1992 and 1999, the rate of single-victim student homicides decreased significantly ( $P = .03$ ); however, homicide rates for students killed in multiple-victim events increased ( $P = .047$ ). Most events occurred around the start of the school day, the lunch period, or the end of the school day. For 120 (54.5%) of the incidents, respondents reported that a note, threat, or other action potentially indicating risk for violence occurred prior to the event. Homicide offenders were more likely than homicide victims to have expressed some form of suicidal behavior prior to the event (odds ratio [OR], 6.96; 95% confidence interval [CI], 1.96-24.65) and been bullied by their peers (OR, 2.57; 95% CI, 1.12-5.92). CONCLUSIONS: Although school-associated violent deaths remain rare events, they have occurred often enough to allow for the detection of patterns and the identification of potential risk factors. This information may help schools respond to this problem.

Andersson A, Eden P, Lindgren D *et al.* Gene expression profiling of leukemic cell lines reveals conserved molecular signatures among subtypes with specific genetic aberrations. *Leukemia* 2005; 19(6):1042-50. Abstract: Hematologic malignancies are characterized by fusion genes of biological/clinical importance. Immortalized cell lines with such aberrations are today widely used to model different aspects of leukemogenesis. Using cDNA microarrays, we determined the gene expression profiles of 40 cell lines as well as of primary leukemias harboring 11q23/MLL rearrangements, t(1;19)[TCF3/PBX1], t(12;21)[ETV6/RUNX1], t(8;21)[RUNX1/CBFA2T1], t(8;14)[IGH@/MYC], t(8;14)[TRA@/MYC], t(9;22)[BCR/ABL1], t(10;11)[PICALM/MLLT10], t(15;17)[PML/RARA], or inv(16)[CBFB/MYH11]. Unsupervised classification revealed that hematopoietic cell lines of diverse origin, but with the

same primary genetic changes, segregated together, suggesting that pathogenetically important regulatory networks remain conserved despite numerous passages. Moreover, primary leukemias cosegregated with cell lines carrying identical genetic rearrangements, further supporting that critical regulatory pathways remain intact in hematopoietic cell lines. Transcriptional signatures correlating with clinical subtypes/primary genetic changes were identified and annotated based on their biological/molecular properties and chromosomal localization. Furthermore, the expression profile of tyrosine kinase-encoding genes was investigated, identifying several differentially expressed members, segregating with primary genetic changes, which may be targeted with tyrosine kinase inhibitors. The identified conserved signatures are likely to reflect regulatory networks of importance for the transforming abilities of the primary genetic changes and offer important pathogenetic insights as well as a number of targets for future rational drug design.

Andersson N, Cockcroft A, Ansari N *et al.* Household cost-benefit equations and sustainable universal childhood immunisation: a randomised cluster controlled trial in south Pakistan. *BMC Public Health* 2005; 5:72. Abstract: BACKGROUND: Household decision-makers decide about service use based largely on the costs and perceived benefits of health interventions. Very often this leads to different decisions than those imagined by health planners, resulting in under-utilisation of public services like immunisation. In the case of Lasbela district in the south of Pakistan, only one in every ten children is immunised despite free immunisation offers by government health services. METHODS/DESIGN: In 32 communities representative of Lasbela district, 3344 households participated in a baseline survey on early child health. In the 18 randomly selected intervention communities, we will stimulate discussions on the household cost-benefit equation, as measured in the baseline. The reference (control) communities will also participate in the three annual follow-up surveys, feedback of the general survey results and the usual health promotion activities relating to immunisation, but without focussed discussion on the household cost-benefit equations. DISCUSSION: This project proposes knowledge translation as a two-way communication that can be augmented by local and international evidence. We will document cultural and contextual barriers to immunisation in the context of household cost-benefit equations. The project makes this information accessible to health managers, and reciprocally, makes information on immunisation effects and side effects available to communities. We will measure the impact of this two-way knowledge translation on immunisation uptake.

Andrade LO, Baretta IC, Gomes CF, Canuto OM. Public health policies as guides for local public policies: the experience of Sobral-Ceara, Brazil. *Promot Educ* 2005;

Suppl 3:28-31.

Abstract: The accelerated urbanisation process that Brazil has gone through in the last 50 years has given rise to daunting challenges for public managers, especially in terms of local public policy management for the building of "healthy cities". In Sobral, a municipality of 173,000 inhabitants in Ceara in the North-eastern region of Brazil, a number of municipal policies were initiated beginning in 1997, many in partnership with the federal and state governments. They were inspired by the vision of a healthy and equitable city and were marked by strategic planning and the implementation of intersectoral projects. This article lays out some of the actions and their results, including an increase in the public supply of drinking water from 65% to 97% of households; an increase in sewage networks from 7% to 65%; an increase in public refuse collection from 42% to 90%; the expansion of green areas; the construction of nine kilometres of bicycle paths; the universalisation of integral health care through the Family Health Strategy through a network with specialised out-patient and hospital services; and a 148% increase in the number of children enrolled in primary school. These initiatives also resulted in the improvement of quality of life indicators, including a reduction in infant mortality from 61.4 to 19.0 per thousand live births, a drop in the mortality rate from traffic accidents from 33.40 per 100,000 inhabitants in 2001 to 15.25 in 2003; and a jump in literacy rates among children in the first cycle of primary school from 40 to 90.7%. In the present article, the authors describe some of the successful strategies and projects initiated between 1997 and 2003, and discuss how this experience could be reproduced in other communities across Brazil and around the world.

Andrade RC, Silva VA, Assumpcao FB Jr. Preliminary data on the prevalence of psychiatric disorders in Brazilian male and female juvenile delinquents. *Braz J Med Biol Res* 2004; 37(8):1155-60. Abstract: The aim of the present investigation was to study the prevalence of psychiatric disorders in a sample of delinquent adolescents of both genders and to compare the prevalence between genders. A total of 116 adolescents (99 males and 17 females) aged 12 to 19 on parole in the State of Rio de Janeiro were interviewed using the screening interview based on the Schedule for Affective Disorders and Schizophrenia for School-Age Children -- Present and Lifetime (KSADS-PL). Data were collected between May 2002 and January 2003. Of 373 male and 58 female adolescents present in May 2002 in the largest institution that gives assistance to adolescents on parole in the city of Rio de Janeiro, 119 subjects were assessed (three of them refused to participate). Their average age was 16.5 years with no difference between genders. The screening interview was positive for psychopathology for most of the sample, with the frequencies of the suggested more prevalent psychiatric

disorders being 54% for attention-deficit/hyperactivity disorder, 77% for conduct disorder, 41% for oppositional defiant disorder, 57% for anxiety disorder 57, 60% for depressive disorder 60, 63% for illicit drug abuse, and 58% for regular alcohol use. Internalizing disorders (depressive disorders, anxiety disorders and phobias) were more prevalent in the female subsample. There was no significant difference in the prevalence of illicit drug abuse between genders. There were more male than female adolescents on parole and failure to comply with the sentence was significantly more frequent in females. The high prevalence of psychopathology suggested by this study indicates the need for psychiatric treatment as part of the prevention of juvenile delinquency or as part of the sentence. However, treatment had never been available for 93% of the sample in this study.

Andrzejak RG, Widman G, Lehnertz K, Rieke C, David P, Elger CE. The epileptic process as nonlinear deterministic dynamics in a stochastic environment: an evaluation on mesial temporal lobe epilepsy. *Epilepsy Res* 2001; 44(2-3):129-40. Abstract: The theory of deterministic chaos addresses simple deterministic dynamics in which nonlinearity gives rise to complex temporal behavior. Although biological neuronal networks such as the brain are highly complicated, a number of studies provide growing evidence that nonlinear time series analysis of brain electrical activity in patients with epilepsy is capable of providing potentially useful diagnostic information. In the present study, this analysis framework was extended by introducing a new measure  $\xi$ , designed to discriminate between nonlinear deterministic and linear stochastic dynamics. For the evaluation of its discriminative power,  $\xi$  was extracted from intracranial multi-channel EEGs recorded during the interictal state in 25 patients with unilateral mesial temporal lobe epilepsy. Strong indications of nonlinear determinism were found in recordings from within the epileptogenic zone, while EEG signals from other sites mainly resembled linear stochastic dynamics. In all investigated cases, this differentiation allowed to retrospectively determine the side of the epileptogenic zone in full agreement with results of the presurgical workup.

Angeles-Llerenas A, Bello MA, Dirce G, Salinas MA. [Argentina, Brazil and Mexico. Biomedical research and the defense of a single standard of attention in developing countries]. *Rev Invest Clin* 2004;

56(5):675-85.

Abstract: In the Helsinki Declaration, which established the ethical principles for research with human subjects, article 5 states, "...concern about the well-being of human beings should always come before the interests of science and of society..." Research proposals should include this commitment, both in developed and developing countries. In countries like Argentina, Brazil and Mexico, much of the population experience situations of great injustice, including a lack of equal access to health care. In some cases, sectors of the pharmaceutical industry may see these deficiencies as offering opportunities for carrying out research and achieving economic profits, something which carries the risk of perpetuating and even intensifying the unjust situations and violations of human rights--these population groups already suffer from. This situation implies the need for commitment to and ethical reflection upon human rights related to health. Agreements are needed between the actors involved in health research: sources of funding, researchers, public policy makers, and the study subjects themselves, in order to protect the latter's rights, including continuity of medical treatment for research subjects, when necessary.

Angelides S. Historicizing affect, psychoanalyzing history: pedophilia and the discourse of child sexuality. *J Homosex* 2003; 46(1-2):79-109. Abstract: Within the last two decades in Australia, Britain, and the United States, we have seen a veritable explosion of cultural panic regarding the problem of pedophilia. Scarcely a day passes without some mention in the media of predatory pedophiles or organized pedophile networks. Many social constructionist historians and sociologists have described this incitement to discourse as indicative of a moral panic. The question that concerns me in this article is: If this incitement to discourse is indicative of a moral panic, to what does the panic refer? I begin by detailing, first, how social constructionism requires psychoanalytic categories in order to understand the notion of panic, and second, how a psychoanalytic reading of history might reveal important unconscious forces at work in the current pedophilia "crisis" that our culture refuses to confront. Here, I will suggest a repressed discourse of child sexuality is writ large. I will argue that the hegemonic discourse of pedophilia is contained largely within a neurotic structure and that many of our prevailing responses to pedophilia function as a way to avoid tackling crucial issues about the reality and trauma of childhood sexuality.

Ani C, Garralda E. Developing primary mental healthcare for children and adolescents. *Curr Opin Psychiatry* 2005; 18(4):440-4. Abstract: PURPOSE OF REVIEW: Governmental initiatives to enhance child and adolescent mental healthcare are giving renewed impetus to work in primary care. This review identifies and discusses

critically new findings in this area. RECENT FINDINGS: Research reviews and new studies continue to highlight the burden of unidentified and hence untreated psychopathology among children attending primary care. Expression of parental concern appears to provide important help in improving recognition. Shared protocols have been developed for primary care use for clinical conditions such as attention deficit hyperactivity disorder, but adherence to protocols is still limited. Randomized controlled trials have shown the feasibility and efficacy of suitably adapted therapeutic interventions for adolescent depression in primary healthcare and in educational settings. Surveys indicate a significant amount of child and adolescent mental health work by social services in countries such as the UK, and attest to the usefulness of protocols to attend to children in foster care. The new role of primary mental health worker has the potential to help support the interface between primary and specialist child and adolescent mental health services. SUMMARY: There is increased interest in further clarifying and enhancing the role of primary care child and adolescent mental health services.

Anthuber S, Hepp H. [Child and adolescent gynecology. Introduction to the focal topic 'Child and adolescent gynecology']. *Gynakol Geburtshilfliche Rundsch* 2003; 43(3):129-30. Abstract: Valuable knowledge from the subspecialty of child and adolescent gynecology is of considerable

importance for the clinically active pediatrician and gynecologist. Focal topics such as sexual violence to children and young adults, undesired pregnancies and pregnancy termination should not only be made known in the media, but also to specialists, so that successful prevention and treatment can be carried out. Furthermore, endocrinological problems and genital malformations in adolescence should be detectable and treatable.

Aouina H, El Gharbi L, Fakhfakh R *et al.* [Smoking cessation program in Tunisia: experience of a respiratory service.]. *Int J Tuberc Lung Dis* 2002; 6(12):1123-7.

Abstract: A tobacco cessation programme was recently introduced into medical practice in Tunisia. The medical staff in the pulmonary disease ward at Charles Nicolle Hospital, Tunis, has been the first to implement such a programme for people motivated to quit smoking. This programme has been run for 3 years in the respiratory disease out-patient department. It acts essentially against psychological and pharmacological dependence on tobacco. The results obtained were very encouraging: 298 smokers have participated in this programme. The global success rate at 12 months of tobacco withdrawal was about 25% for people who were followed up, and 17% for the whole sample. Medical help for smoking cessation should be more widely promoted in Tunisia to increase the number of smokers who consult and improve the quality of medical intervention.

Appelbaum PS. Law & psychiatry: Third-party suits against therapists in recovered-memory cases. *Psychiatr Serv* 2001; 52(1):27-8.

Appelbaum PS. The 'quiet' crisis in mental health services. *Health Aff (Millwood)* 2003; 22(5):110-6. Abstract: The failure of insurers and managed care organizations to reimburse providers of mental health services for the costs of care has led to a crisis in access to these services. Using the situation in Massachusetts as a case example, this paper explores the impact of this defunding. Unable to sustain continued losses, hospitals are closing psychiatric units, and outpatient services are contracting or closing altogether. The situation has been compounded by the withdrawal of many practitioners from managed care networks and cuts in public-sector mental health services. Unless purchasers demand effective coverage of mental health treatment, mental health services will likely continue to wither away.

Arachchi JK, Sumanasena SP, de Silva KS. Clinical examination in paediatrics at final MBBS: views of children and their parents. *Ceylon Med J* 2003; 48(1):12-4.

Abstract: INTRODUCTION: The final examination in paediatrics for medical undergraduates in Sri Lanka

consists of a written and a clinical component. Each candidate at the clinical component sees one long case and two short cases. OBJECTIVES: To assess the views of the bystanders regarding their sick children participating at a clinical examination, and to evaluate the children's perceptions of the clinical component. METHODS: An interviewer-administered questionnaire was discussed separately with the participating children and their bystanders at the final year examination in paediatrics of the Faculty of Medicine, Colombo, in 1999. RESULTS: 116 patients participated at the clinical examination in paediatrics. 107 (92%) of the bystanders were the children's mothers. Informed consent had not been obtained for use in the examination from 59 (51%) of the children's mothers. Seven (6%) were not satisfied with the way their children were handled by the candidates, and 25 (21.5%) showed concern about the number of candidates examining their child. Bystanders who participated at the long cases were inconvenience more than those in the short cases. 34 children above the age of 5 years were also interviewed. An explanation regarding the examination had not been given to 31 (92%) of them. Six children (17%) said they were examined for too long. A majority of the bystanders welcomed the payments received and all of them were satisfied with the medical students' conduct and politeness. All of them agreed that this form of clinical examination was a good method of evaluating a student's professional competence. CONCLUSIONS: Several aspects of the clinical component of the final examination in paediatrics for medical undergraduates need to be improved to minimise the inconvenience experienced by the children and their parents.

Arana E, Marti-Bonmati L, Bautista D, Paredes R. [Diagnosis of calvarial lesions. Feature selection by neural network and logistic regression]. *Neurocirugia (Astur)* 2003; 14(5):377-84.

Abstract: OBJECTIVES: To establish the minimum set of features needed in the diagnosis of calvarial lesions using computed tomography (CT) and to assess the accuracy of logistic regression (LR) and artificial neural networks (NN) for their diagnosis. MATERIAL AND METHODS: 167 patients with calvarial lesions as the only known disease were enrolled. The clinical and CT data were used for LR and NN models. Both models were tested with the jackknife method. The final results of each model were compared using the area under ROC curves (A<sub>2</sub>). RESULTS: The lesions were 73.1 % benign and 26.9% malignant. There was no statistically significant difference between LR and NN in differentiating malignancy. In characterizing the histologic diagnoses, NN was statistically superior to LR. Important NN features needed for malignancy classification were age and edge definition, and for the histologic diagnoses matrix, marginal sclerosis and age. CONCLUSIONS: A minimum four features is needed to diagnose these lesions, not being important patients' symptoms. NNs offer wide possibilities over

statistics for the calvarial lesions study besides a superior diagnostic performance.

Arana E, Marti-Bonmati L, Bautista D, Paredes R. Qualitative diagnosis of calvarial metastasis by neural network and logistic regression. *Acad Radiol* 2004; 11(1):45-52.

Abstract: **RATIONALE AND OBJECTIVES:** To simplify the diagnostic features used by an artificial neural network compared with logistic regression (LR) in the diagnosis of calvarial metastasis with computed tomography and analyze their accuracy. **MATERIALS AND METHODS:** Twenty-one of 167 patients with calvarial lesions were found to have metastasis. Clinical and computed tomography data were used for LR and neural network models. Both models were tested with the leave-one-out method. The final results of each model were compared using the area under receiver operating characteristic curve (Az). **RESULTS:** The neural network identified metastasis significantly more successfully than LR with an Az of 0.9324 +/- 0.0386 versus 0.9192 +/- 0.0373, P = .01. The most important features selected by the LR and neural network were age and edge definition. **CONCLUSION:** Neural networks offer wide possibilities over statistics for the study of calvarial metastases other than their minimum clinical and radiologic features for diagnosis.

Arcos E, Uarac M, Molina I, Repossi A, Ulloa M. [Impact of domestic violence on reproductive and neonatal health]. *Rev Med Chil* 2001; 129(12):1413-24. Abstract: **BACKGROUND:** Domestic violence can have an important influence on mother and child health. **AIM:** To assess the consequences of remote and actual, emotional or physical, domestic violence on the reproductive and newborn health in pregnant women. **MATERIAL AND METHODS:** A longitudinal epidemiological observation from an Urban Primary Health Care Center from Valdivia, Chile, in 1998. Two cohorts were studied: Pregnant women that experienced domestic violence (index group) and pregnant women not exposed to domestic violence (control group). Women were followed during pregnancy and at labor. The newborn was also assessed. **RESULTS:** The index group had a higher relative risk (RR) for impending abortion (RR 1.44, 95% confidence interval (CI): 1.07-1.93), hypertensive syndrome of pregnancy (RR 1.5, 95% CI: 1.18-1.96), intrahepatic cholestasis (RR 1.5, 95% CI: 1.1-1.94). Women that experienced violence during pregnancy had a higher risk of urinary tract infection (RR 2.88, 95% CI: 1.28-6.43), intrauterine growth retardation (RR 3.7, 95% CI: 1.77-7.93) and intrahepatic cholestasis. Newborns from the index group had lower weight, size and gestational age. **CONCLUSIONS:** Domestic violence is associated with hypertension during pregnancy and intrauterine growth retardation. The incorporation of bio-psychological evaluation and monitoring systems could attenuate the consequences

of domestic violence.

Argyropoulos C, Nikiforidis GC, Theodoropoulou M *et al.* Mining microarray data to identify transcription factors expressed in naive resting but not activated T lymphocytes. *Genes Immun* 2004; 5(1):16-25. Abstract: Transcriptional repressors controlling the expression of cytokine genes have been implicated in a variety of physiological and pathological phenomena. An unknown repressor that binds to the distal NFAT element of the interleukin-2 (IL-2) gene promoter in naive T-helper lymphocytes has been implicated in autoimmune phenomena and has emerged as a potentially important factor controlling the latency of HIV-1. The aim of this paper was the identification of this repressor. We resorted to public microarray databases looking for DNA-binding proteins that are present in naive resting T cells but are downregulated when the cells are activated. A Bayesian data mining statistical analysis uncovered 25 candidate factors. Of the 25, NFAT4 and the oncogene ets-2 bind to the common motif AAGGAG found in the HIV-1 LTR and IL-2 probes. Ets-2 binding site contains the three G's that have been shown to be important for binding of the unknown factor; hence, we considered it the likeliest candidate. Electrophoretic mobility shift assays confirmed cross-reactivity between the unknown repressor and anti-ets-2 antibodies, and cotransfection experiments demonstrated the direct involvement of Ets-2 in silencing the IL-2 promoter. Designing experiments for transcription factor analysis using microarrays and Bayesian statistical methodologies provides a novel way toward elucidation of gene control networks.

Arie S. WHO takes up issue of child abuse. *BMJ* 2005; 331(7509):129.

Ariza AJ, Greenberg RS, Unger R. Childhood overweight: management approaches in young children. *Pediatr Ann* 2004; 33(1):33-8. Abstract: Management of overweight in young children may be our best opportunity for confronting the nationwide epidemic of childhood obesity. Doing so will require all health care providers to improve their identification, assessment, and guidance on this issue. As a group, we must make it a priority to obtain height and weight measurements on every child and to interpret them correctly. We must be comprehensive in our medical investigation in order to uncover identifiable causes and recognize comorbidities. Most of all, we must motivate families, as a whole, to confront this issue with us by increasing physical activity, decreasing sedentary behaviors, and improving eating practices. As health professionals in a society that is not yet poised to fight this epidemic, we must lead the way.

Armour KL, Callister LC. Prevention of triplets and higher

order multiples: trends in reproductive medicine. *J Perinat Neonatal Nurs* 2005; 19(2):103-11.

Abstract: In the United States and throughout the world, today's healthcare providers are challenged by the risks of multiple gestation pregnancy. Assisted reproductive technologies (ARTs) often used to treat infertility raise ethical issues including informed consent, veracity, and nonmalificence. In the United States, there is the need to improve maternal and fetal/neonatal mortality and morbidity by proposing legislation regulating ART and supporting single embryo transfers with no more than 2 such transfers. Beginning with the diagnosis of infertility, providers have a responsibility to educate, inform, and treat infertile couples. From the moment pregnancy with multiples is confirmed, these families are faced with incredible stressors including decision making on multifetal or selective reduction. Full disclosure of risks involved throughout the course of care should be discussed and documented in the record and plan of care. Currently in the United States, legislation does not regulate ART, including ovulation induction/enhancement and in vitro fertilization. Although the United States does have self-regulation via limited reporting through their professional organization and the Centers for Disease Control and Prevention, an unlimited number of embryos may be transferred. Unfortunately, many healthcare providers have not recognized the responsibility and burden placed on families and society as a whole. Lack of regulation means women may become pregnant with high order multiples, which raises serious moral and ethical issues.

Armstrong DB, Cole WG. Can child accidents be prevented in your community? *Am J Public Health* 2004; 94(6):940, 942.

Armstrong K, Kerns KA. The assessment of parent needs following paediatric traumatic brain injury. *Pediatr Rehabil* 2002; 5(3):149-60.

Abstract: The paediatric version of the Family Needs Questionnaire was administered to parents of children with traumatic brain injuries (TBI) a year or more post-injury. Parents of diabetic children (DIAB) and parents of orthopaedically (ORTHO) injured children were included as control groups. Parents rated items on their importance and how well these needs have been met. The ORTHO group rated significantly fewer items as important relative to the TBI and DIAB groups (who endorsed a similar number of items). Of those items rated as important, TBI parents' needs were more likely to remain unmet relative to both the DIAB and the ORTHO groups: out of 28 items rated as important, TBI parents report that 19 needs are still unmet. DIAB and ORTHO parents more consistently reported their needs as met. Needs most often rated as unmet for TBI parents include the needs for health/medical information, professional support, community support networks, and the need to be involved in their child's

care. These results present important findings for TBI rehabilitation professionals. Future studies need to investigate whether TBI parents' needs are unmet because of the lack of community resources, or if available resources do not adequately target the needs of the TBI parents.

Armstrong TD, Costello EJ. Community studies on adolescent substance use, abuse, or dependence and psychiatric comorbidity. *J Consult Clin Psychol* 2002; 70(6):1224-39.

Abstract: A literature review on community studies of adolescent substance use, abuse, or dependence (SU/AID) and psychiatric comorbidity yielded 22 articles from 15 studies with information on rates, specificity, timing, and differential patterns of comorbidity by gender, race/ethnicity, and other factors. Results revealed that 60% of youths with SU/AID had a comorbid diagnosis, and conduct disorder (CD) and oppositional defiant disorder (not attention-deficit/hyperactivity disorder) were most commonly associated with SU/AID, followed by depression. Child psychopathology (particularly CD) was associated with early onset of substance use and abuse in later adolescence. The authors suggest that available data relevant to SU/AID and psychiatric comorbidity can be used to better address such questions.

Arnold EM, Kirk RS, Roberts AC, Griffith DP, Meadows K, Julian J. Treatment of incarcerated, sexually-abused adolescent females: an outcome study. *J Child Sex Abus* 2003; 12(1):123-39.

Abstract: This study examined the psychosocial functioning of 100 adolescent females (ages 12-17) sentenced to secure care in a southeastern state and the impact of gender-specific, cognitive-behavioral therapy (CBT) intervention on the psychosocial functioning of subjects who reported a history of sexual abuse. The Multidimensional Adolescent Assessment Scale (MAAS) was used to assess psychosocial functioning. Pre-test scores on the MAAS revealed significantly higher scores on 12 of 16 dimensions of psychosocial functioning and higher rates of serious criminal behavior for youth who subsequently disclosed sexual abuse histories as compared to those without such histories. At post-test, statistically significant improvements in psychosocial functioning were observed on 14 of 16 MAAS subscales for those who received the CBT intervention. Thus, incarcerated female adolescents who reported a history of sexual abuse demonstrated more impairment in their functioning as compared to those without a reported history of sexual abuse and responded positively to gender-specific, CBT-based intervention.

Arnold LE. Turn-of-the-century ethical issues in child psychiatric research. *Curr Psychiatry Rep* 2001; 3(2):109-14.

Abstract: National concern in 2000 about increased psychoactive drug prescription for preschoolers accentuated the 1990s thrust for more pharmacologic research in children. Preschoolers are prescribed potent drugs without adequate evidence for efficacy or safety at this plastic age of the rapidly developing brain. Implementation of needed preschool research poses special ethical complications. Children with mental disorder qualify for special protection under both rubrics. Parental informed consent is crucial for preschoolers, who appear incapable of assent because of their preoperational, magical, animistic, egocentric thinking, with inability to comprehend relative risks and benefits. Whether they can dissent is an open question. Possibly for research with direct benefit outweighing the risk, parental permission/consent could override attempted preschooler dissent. Subject recompense should be adjusted for age differences in perception of amount, although parent reimbursement needs to be realistic. Insurance for research risk is desirable. Placebo controls appear justified for preschoolers because there is little evidence base to say that a proven effective treatment already exists. Disruptive behavior disorders, including attention-deficit/hyperactivity, have enough evidence of preschool diagnostic validity to justify therapeutic trials. In preschool pharmacologic research, a brief trial of a nonpharmacologic treatment should precede the drug trial to ensure that placebo responders and responders to the alternative treatment are not exposed to drug risk.

Arnold RW. Macular hole without hemorrhages and shaken baby syndrome: practical medicolegal documentation of children's eye trauma. *J Pediatr Ophthalmol Strabismus* 2003; 40(6):355-7.

Arntzen A, Nybo Andersen AM. Social determinants for infant mortality in the Nordic countries, 1980-2001. *Scand J Public Health* 2004; 32(5):381-9. Abstract: AIM: Social equity in health is an important goal of public health policies in the Nordic countries. Infant mortality is often used as an indicator of the health of societies, and has decreased substantially in the Nordic welfare states over the past 20 years. To identify social patterns in infant mortality in this context the authors set out to review the existing epidemiological literature on associations between social indicators and infant mortality in Denmark, Finland, Norway, and Sweden during the period 1980-2000. METHODS: Nordic epidemiological studies in the databases ISI Web of Science, PubMed, and OVID, published between 1980 and 2000 focusing on social indicators of infant, neonatal, and postneonatal mortality, were identified. The selected keywords on social indicators were: education, income, occupation, social factors, socioeconomic status, social position, and social class. RESULTS: Social inequality in infant mortality was reported from Denmark, Finland, Norway, and Sweden, and it was found that these

increased during the study period. Post-neonatal mortality showed a stronger association with social indicators than neonatal mortality. Some studies showed that neonatal mortality was associated with social indicators in a non-linear fashion, with high rates of mortality in both the lowest and highest social strata. The pattern differed, however, between countries with Finland and Sweden showing consistently less social inequalities than Denmark and Norway. While the increased inequality shown in most studies was an increase in relative risk, a single study from Denmark demonstrated an absolute increase in infant mortality among children born to less educated women. CONCLUSIONS: Social inequalities in infant mortality are observed in all four countries, irrespective of social indicators used in the studies. It is, however, difficult to draw inferences from the comparisons between countries, since different measures of social position and different inclusion criteria are used in the studies. Nordic collaborative analyses of social gradients in infant death are needed, taking advantage of the population-covering registers in longitudinal designs, to explore the mechanisms behind the social patterns in infant mortality.

Arons J. "In a black hole": the (negative) space between longing and dread: Home-based psychotherapy with a traumatized mother and her infant son. *Psychoanal Study Child* 2005; 60:101-27. Abstract: This paper offers fragments from the first year of a home-based mother-baby psychotherapy, in which I attempted to help a traumatized and dissociated mother to emotionally engage with her infant son. The treatment was organized in part around certain developmental objectives common to both attachment and psychoanalytic theory. These include: The ability to name and metabolize feelings, to evoke a soothing maternal introject, and to relate to the partner's mind as a separate, understandable center of initiative and intention. In addition, attachment theory, with its emphasis on the critical psychobiological role of containing fear and distress in infancy, was a useful guide in formulating the treatment. The paper reviews research findings on mother-infant pairs described as frightened-disorganized, discusses some of the challenges encountered in home-based mother-infant psychotherapy and then discusses the case of Mary and John. The case illustrates how mother-infant psychotherapy may interrupt the intergenerational transmission of disorganized attachment by working within the couple to name, metabolize and flexibly respond to painful, dissociated or frightening experiences.

Arseneault L, Cannon M, Murray R, Poulton R, Caspi A, Moffitt TE. Childhood origins of violent behaviour in adults with schizophreniform disorder dagger. *Br J Psychiatry* 2003; 183:520-5. Abstract: BACKGROUND: People with psychosis have an elevated risk of violence. AIMS: To examine

whether violent behaviour in adults with psychosis can be accounted for by psychotic symptoms or physical aggression in childhood. **METHOD:** We used data from a prospective longitudinal study of a complete birth cohort born in New Zealand. When cohort members were 26 years old, information was obtained on past-year psychiatric diagnosis of schizophreniform disorder and on violent behaviour. Childhood psychotic symptoms were measured at age 11 years using a diagnostic interview, and childhood physical aggression was assessed by teachers when cohort members were aged 7, 9 and 11 years. **RESULTS:** Participants with schizophreniform disorder were more likely to be violent than participants without, even after controlling for sociodemographic variables and concurrent substance dependence disorders. Childhood psychotic symptoms were a strong risk factor for violence in adults with schizophreniform disorder, as was childhood physical aggression, although to a lesser extent. **CONCLUSIONS:** Violence by individuals with schizophreniform disorder could be prevented by monitoring early signs of psychotic symptoms and by controlling childhood physical aggression.

Arterburn T. Using hidden cameras to monitor suspected parental abuse. *J Healthc Prot Manage* 2001; 17(2):80-7.

**Abstract:** In using hidden cameras to monitor suspected parental abuse a security requirement or an invasion of privacy? Covert surveillance of patients suspected of having Munchausen syndrome by proxy at an Atlanta children's hospital resulted in considerable media scrutiny when researchers published their findings. This article presents details of the research, the involvement of security officers, and the reactions of local authorities and health officials.

Aryan HE, Jandial R, Bennett RL, Masri LS, Lavine SD, Levy ML. Gunshot wounds to the head: gang- and non-gang-related injuries and outcomes. *Brain Inj* 2005; 19(7):505-10.

**Abstract:** **PRIMARY OBJECTIVE:** This study examined the differences between gang and non-gang-related incidents of penetrative missile injuries in terms of demographics, motivation, intra-cranial pathology, transit time, injury time and clinical outcome. **RESEARCH DESIGN:** Retrospective and prospective chart review. **METHODS AND PROCEDURES:** Between 1985-1992, 349 patients with penetrating missile injuries to the brain presenting to LAC-USC were studied. **EXPERIMENTAL INTERVENTIONS:** Inclusion criteria were implemented to keep the cohort as homogenous as possible. Patients excluded were those with multiple gunshot wounds, non-penetrating gunshot wounds to the head, systemic injuries and cases in which the motivation for the incident was unknown. **MAIN OUTCOMES AND RESULTS:** Gang-related shooting slightly out-numbered non-gang-related incidents. Demographic analysis showed both a male and Hispanic predominance for both gang-

and non-gang-related victims and significant differences in gender, race and age. Occipital entrance sites were more common in the gang-related vs temporal entrance sites in the non-gang-related. Mean transit time to the emergency department for gang-related shootings was less than non-gang-related shootings (24.4 vs 27.8 minutes). Most shooting incidents took place between 6pm and 3am. No difference between survival and outcome was noted between gang and non-gang victims. **CONCLUSIONS:** Significant differences were found between gang- and non-gang-related shooting victims in terms of demographics, entrance site and transit time. No difference was found between injury time, survival and outcome between gang and non-gang populations.

Ashby SL, Rich M. Video killed the radio star: the effects of music videos on adolescent health. *Adolesc Med Clin* 2005; 16(2):371-93, ix.

**Abstract:** Since its inception half a century ago, rock and roll has been the music of youth and rebellion, of freedom, and of idealism. Popular music has been a reflection of, and inspiration for, youth movements, fads, and lifestyles that can include health risk behaviors, such as sex, drugs, and interpersonal violence. This article summarizes the health-related content of music videos, and discusses associations between music videos and adolescent health risks.

Asherson P. Attention-Deficit Hyperactivity Disorder in the post-genomic era. *Eur Child Adolesc Psychiatry* 2004; 13 Suppl 1:150-70.

**Notes:** CORPORATE NAME: IMAGE Consortium **Abstract:** **BACKGROUND:** ADHD is a common and complex genetic disorder. Genetic risk factors are expected to be multiple, have small effect sizes when considered individually and to interact with each other and with environmental factors. **OBJECTIVE:** To describe the difficulties involved in the genetic investigation of such a complex disorder and give a perspective for the future. **METHODS:** Review based on empirical literature and project description. **RESULTS:** Considerable progress has been achieved through the association analysis of candidate gene loci. Linkage scans using affected sibling pairs have identified a number of potential loci that may lead to the identification of novel genes of moderate effect size. Quantitative trait locus (QTL) approaches provide powerful complementary strategies that have the potential to link the categorical disorder to continuously distributed traits associated more closely with underlying genetic liability in the general population. Success in identifying some associated genes has been complemented by functional studies that seek to understand the mode of action of such

genes. CONCLUSION: Progress in understanding the mechanisms involved has not been straightforward and many inconsistencies have arisen. In order to take advantage of the potential for progress that stems from the genetic findings it will be important to draw upon a variety of approaches and experimental paradigms. A functional genomic approach to ADHD means that investigation of gene function is carried out at various levels of analysis, not only at the level of molecular and cellular function but also at the level of psychological processes, neuronal networks, environmental interactions and behavioural outcomes.
