Abstract: We present Bayesian hierarchical spatial models for spatially correlated small-area health service outcome and utilization rates, with a particular emphasis on the estimation of both measured and unmeasured or unknown covariate effects. This Bayesian hierarchical model framework enables simultaneous modeling of fixed covariate effects and random residual effects. The random effects are modeled via Bayesian prior specifications reflecting spatial heterogeneity globally and relative homogeneity among neighboring areas. The model inference is implemented using Markov chain Monte Carlo methods. Specifically, a hybrid Markov chain Monte Carlo algorithm (Neal, 1995, Bayesian Learning for Neural Networks; Gustafson, MacNab, and Wen, 2003, Statistics and Computing, to appear) is used for posterior sampling of the random effects. To illustrate relevant problems, methods, and techniques, we present an analysis of regional variation in intraventricular hemorrhage incidence rates among neonatal intensive care unit patients across Canada.

Macones GA, Hausman N, Edelstein R, Stamilio DM, Marder SJ. Predicting outcomes of trials of labor in women attempting vaginal birth after cesarean delivery: a comparison of multivariate methods with neural networks. *Am J Obstet Gynecol* 2001; 184(3):409-13.

Abstract: OBJECTIVE: Our aim was to assess the utility and effectiveness of a neural network for predicting the likelihood of success of a trial of labor, relative to standard multivariate predictive models.

STUDY DESIGN: We identified 100 failed trials of labor and 300 successful trials of labor in women with a prior cesarean delivery performed at our institution. Information was collected on >70 potential predictors of labor outcomes from the medical records, including demographic, historical, and past obstetric information, as well as information from the index pregnancy. Bivariate analyses comparing women in whom a trial of labor failed with those whose trial succeeded were performed. These initial analyses were used to select variables for inclusion into our multivariate predictive model. From the same data we trained and tested a neural network, using a back-propagation algorithm. The test characteristics of the multivariate predictive model and the neural network were compared. RESULTS: From the bivariate analysis a history of substance abuse (adjusted odds ratio, 0.27; 95% confidence interval, 0.09-0.80), a successful prior vaginal birth after cesarean delivery (adjusted odds ratio, 0.13; 95% confidence interval, 0.05-0.31), cervical dilatation at admission (adjusted odds ratio, 0.53; 95% confidence interval, 0.31-0.88), and the need for labor augmentation (adjusted odds ratio, 2.15; 95% confidence interval, 1.14-4.06) were ultimately discovered to be important in predicting the likelihood of the success or failure of a trial of labor. With these variables in the predictive model the sensitivity of the derived rule for predicting failure was 77%, the specificity was 65%, and the overall accuracy was 69%. We also built a network using the 4 variables that were included in the final multivariate model. We were unable to achieve the same degree of sensitivity and specificity that we observed with the regression-based predictive model (sensitivity and specificity, 59% and 44%). CONCLUSION: In this study a standard multivariate model was better able to predict outcome in women attempting a trial of labor.

MacPhee M. Using evidence-based practice to create a venous access team: the Venous Access Task Force of the Children's Hospital of Denver. *J Pediatr Nurs* 2002; 17(6):450-4.

Notes: CORPORATE NAME: Venous Access Task Force

Abstract: The following article is an example of evidence-based practice applied to an institutional Quality Improvement (QI) project. QI originated in the 1980s and is best associated with the work of W. Deming (1986). It is also known as Continuous Quality Improvement, because a major principle of this approach is constant improvement of services or products. This improvement process contains other critical components: scientific method, employee participation and teamwork, accountable leadership,

appropriate training and ongoing education, and client focus (Demming, 1986). QI has been globally successful and has helped transform American industry, including health care services. The following clinically based project illustrates the application of QI concepts and evidence-based practice to enhance outcomes.

MacQueen G, Nagy T, Santa Barbara J, Raichle C. 'Iraq Water Treatment Vulnerabilities': a challenge to public health ethics. *Med Confl Surviv* 2004; 20(2):109-19. Notes: GENERAL NOTE: KIE: 32 refs. GENERAL NOTE: KIE: KIE Bib: public health; war Abstract: A formerly classified US document, 'Iraq Water Treatment Vulnerabilities,' provides evidence that ill health was knowingly induced in the population of Iraq through the ruination of that country's water purification system. We believe that the uncovering of this document should stimulate the public health community to clarify principles of public health ethics and to formulate statements giving voice to these principles. We propose here two statements, one dealing with the broad issue of public health ethics and international relations, and one dealing specifically with public health ethics and water purification.

Madan A, Beech DJ, Flint L. Drugs, guns, and kids: the association between substance use and injury caused by interpersonal violence. *J Pediatr Surg* 2001; 36(3):440-2. Abstract: BACKGROUND: Drug and alcohol uses have been linked to the frequency of injury events, recurrent hospital admission for injury, and interpersonal violence. Data regarding the association of recent substance use and injury type and frequency in children and young adults are not available. Such data probably would be valuable in planning interventions to prevent substance use and reduce the risks of injuries. METHODS: Evidence of substance use was assessed in trauma patients presenting to the authors' level 1 trauma center over a 6-month interval. Demographic data, mechanisms of injury, revised trauma scores (RTS), injury severity scores (ISS), hospital days, and mortality rate were evaluated. Chi square analysis and 2-tailed, paired t tests were used for statistical analysis. Multivariate logistic regression was utilized to determine the influence of individual variables. RESULTS: From a total group of 743 patients with life-threatening injuries, trauma registry records of 186 patients less than 21 years old were eligible for evaluation, and 126 of these had complete blood and urine drug assessments completed on admission to the trauma center. Forty-two percent (53 of 126) patients tested positive for alcohol or drugs. No patients less than 14 years of age (n = 61) had positive drug screen results. However, in the cohort of patients aged 14 and 15 (n = 17), 71% tested positive. Also, 72% of adolescents (age < 18) who were victims of injuries from gunshot wounds had evidence of substance use. Multivariate analysis showed gunshot

wounds (P <.003) to be associated independently with positive drug screens. No statistical differences were observed in ethnic distribution, ISS, RTS, hospital days, or mortality rate when patients with positive screen results were compared with those without evidence of substance use. CONCLUSIONS: Trauma victims had evidence of substance use in early teen age years especially in the 14 and 15-year-old age groups. Toxicology screening disclosed that substance use is associated strongly with gunshot wounds. Substance use, along with poverty, inadequate family support, and peer pressure are factors that influence injury risk. Interventions to prevent substance use in young children may reduce the risk of injury.

Madden JM, Soumerai SB, Lieu TA, Mandl KD, Zhang F, Ross-Degnan D. Effects of a law against early postpartum discharge on newborn follow-up, adverse events, and HMO expenditures. *N Engl J Med* 2002; 347(25):2031-8.

Notes: CORPORATE NAME: Health maintenance organization

Abstract: BACKGROUND: Concern about harm to newborns from early postpartum discharges led to laws establishing minimum hospital stays in the mid-1990s. We evaluated the effects of an early-discharge protocol (a hospital stay of one postpartum night plus a home visit) in a health maintenance organization (HMO) and a subsequent state law guaranteeing a 48-hour hospital stay. METHODS: Using interrupted-time-series analysis and data on 20,366 mother-infant pairs with normal vaginal deliveries, we measured changes in length of stay, newborn examinations on the third or fourth day of life, and office visits, emergency department visits, and hospital readmissions for newborns. We also examined expenditures for hospitalizations and home-based care. RESULTS: The early-discharge program increased the rate of stays of less than two nights from 29.0 percent to 65.6 percent (P<0.001). The rate declined to 13.7 percent after the state mandate (P<0.001). The rate of newborn examinations on the third or fourth day of life increased from 24.5 percent to 64.4 percent with the program (P<0.001), then dropped to 53.0 percent after the mandate (P<0.001)--changes that primarily reflected changes in the rate of home visits. The rate of nonurgent visits to a health center increased from 33.4 percent to 44.7 percent (P<0.001) after the reduced-stay program was implemented. There were no significant changes in the rate of emergency department visits (quarterly mean, 1.1 percent) or rehospitalizations (quarterly mean, 1.5 percent). Results were similar for a vulnerable subgroup with lower incomes, younger maternal age, a lower level of education, or some combination of these characteristics. Average HMO expenditures on hospital and home-based services decreased by \$90 per delivery with the early-discharge program and increased by \$100 after the mandate. CONCLUSIONS: Neither policy appears to have affected the health outcomes of

newborns. After the mandate, newborns were less likely to be examined as recommended on day 3 or 4. Because of changes in hospital prices, the two policies had minimal effects on HMO expenditures for hospital and home-based services.

Madhavan S. Fosterage patterns in the age of AIDS: continuity and change. *Soc Sci Med* 2004; 58(7):1443-54.

Abstract: An estimated 4 million children, or about 10% of the entire South African population, will be orphaned by the year 2015. There is growing consensus that the extended family system is no longer capable of providing for orphans given severe economic constraints. There is, therefore, an urgency to develop appropriate interventions to support families and take care of these children. This article examines some of the existing literature on child fosterage and uses it to highlight understudied aspects of the current situation of children orphaned through AIDS in South Africa. Of particular concern are the points of continuity and change in fosterage patterns before and after the onset of the epidemic in South Africa. I suggest that an understanding of the short- and long-term consequences for children orphaned by AIDS in South Africa calls for historical contextualisation given that child fostering, both voluntarily and involuntarily, has been a feature of black family life since well before the onset of HIV/AIDS. In addition, I demonstrate the value of examining kinship, family, and networks in order to fully understand the circumstances of fostering these children. The paper concludes with a call for more research on children orphaned by AIDS in South Africa that will provide not only more data, but also enrich theoretical approaches to studying patterns of child fosterage in Africa and elsewhere.

Madlon-Kay DJ, DeFor TA, Egarter S. Newborn length of stay, health care utilization, and the effect of Minnesota legislation. *Arch Pediatr Adolesc Med* 2003; 157(6):579-83.

Abstract: OBJECTIVE: To describe newborn length of stay, postdischarge follow-up, and health care utilization in the context of Minnesota's early discharge legislation. DESIGN AND SETTING: Retrospective study using claims data from a large managed care organization. PARTICIPANTS: Term newborns born from January 1995 through February 1999 (N = 22 944). OUTCOME MEASURES: Newborn length of stay, home or clinic visits within 1 week of discharge (early follow-up), immunizations completed by age 3 months, readmissions within 1 month of discharge, and urgent care or emergency department visits within 2 months of discharge. RESULTS: After enactment of Minnesota's early discharge legislation in 1996, the percentage of newborns with short stays (0-1 days after

vaginal birth or 2-3 days after cesarean birth) decreased from 52% to 16% for vaginally born infants and from 87% to 63% for cesarean-born infants (P =.001). Although the legislation mandated coverage for home visits after short stays, only 12.4% of short-stay newborns had early home visits. Overall, 50% of infants had early home or clinic follow-up; compared with those who did not receive early follow-up, these infants were more likely to have complete immunizations (adjusted odds ratio [OR], 1.09; 95% confidence interval [CI], 1.03-1.14), urgent care or emergency department visits (adjusted OR, 1.22; 95% CI, 1.07-1.39), and readmissions (adjusted OR, 2.49; 95% CI, 2.02-3.08). CONCLUSIONS: Although implementation of Minnesota's early discharge legislation corresponded with significantly increased lengths of stay, very few short-stay infants received the postdischarge care for which coverage was mandated. Our findings indicate, however, that infants at higher risk for adverse outcomes were appropriately identified to receive early follow-up.

Mahalingam S, Meanger J, Foster PS, Lidbury BA. The viral manipulation of the host cellular and immune environments to enhance propagation and survival: a focus on RNA viruses. *J Leukoc Biol* 2002; 72(3):429-39.

Abstract: Virus infection presents a significant challenge to host survival. The capacity of the virus to replicate and persist in the host is dependent on the status of the host antiviral defense mechanisms. The study of antiviral immunity has revealed effective antiviral host immune responses and enhanced our knowledge of the diversity of viral immunomodulatory strategies that undermine these defences. This review describes the diverse approaches that are used by RNA viruses to trick or evade immune detection and response systems. Some of these approaches include the specific targeting of the major histocompatibility complex-restricted antigen presentation pathways, apoptosis, disruption of cytokine function and signaling, exploitation of the chemokine system, and interference with humoral immune responses. A detailed insight into interactions of viruses with the immune system may provide direction in the development of new vaccine strategies and novel antiviral compounds.

Maher J, Macfarlane A. Inequalities in infant mortality: trends by social class, registration status, mother's age and birthweight, England and Wales, 1976-2000.

Health Stat Q 2004; (24):14-22.  
Abstract: This article examines trends in inequalities in infant mortality in England and Wales between 1976 and 2000. It describes variations in neonatal, postneonatal and infant mortality by mother's age, registration status, father's social class, multiplicity and birthweight. Throughout the period, social class differences in mortality were wider in the postneonatal period than the neonatal period and there was considerable variation in infant mortality by age of mother, birthweight and multiplicity within both manual and non-manual groups.

Mahon-Daly P, Andrews GJ. Liminality and breastfeeding: women negotiating space and two bodies. *Health Place* 2002; 8(2):61-76.  
Abstract: It is almost universally accepted that breastfeeding infants is nutritionally superior to bottle-feeding. However, despite this medical advice, in many countries breastfeeding rates remain low and in the UK, rates are relatively static. The literature on breastfeeding has discussed international rates and the broad socio-economic factors influencing these rates. Through an observational study of a group of breastfeeding and non-breastfeeding women in the United Kingdom, this research utilises contemporary theoretical perspectives on the body, space and rites of passage, and investigates the reasons why some breastfeeding mothers may be in a liminal period, and the breastfeeding event itself, at times, a liminal and marginalised act. The paper argues that, for the group studied, breastfeeding is sometimes discouraged by its medicalisation, and that breastmilk and breastfeeding are often considered by mothers to be embarrassing. Many of the women studied regarded certain public and private places to be unacceptable places to breastfeed and claimed to modify their behaviour accordingly. The paper demonstrates the value of conducting locally based qualitative research into breastfeeding experiences, and of using theoretical perspectives from post-medical geography to interpret women's experiences.

Mahoney A, Pargament KI, Tarakeshwar N, Swank AB. Religion in the home in the 1980s and 1990s: a meta-analytic review and conceptual analysis of links between religion, marriage, and parenting. *J Fam Psychol* 2001; 15(4):559-96.  
Abstract: The authors reviewed 94 studies published in journals since 1980 on religion and marital or parental functioning. Meta-analytic techniques were used to quantify religion-family associations examined in at least 3 studies. Greater religiousness appeared to

decrease the risk of divorce and facilitate marital functioning, but the effects were small. Greater Christian conservatism was modestly associated with greater endorsement and use of corporal punishment with preadolescents. Isolated findings suggested that greater parental religiousness relates to more positive parenting and better child adjustment. The scope, meaningfulness, and potential strength of findings were restricted because of reliance on global or single-item measures of religious and family domains. To facilitate more conceptually and methodologically sophisticated research, the authors delineated mechanisms by which the substantive and psychosocial elements of religion could benefit or harm family adjustment.

Mahoney G, Wheeden CA, Perales F. Relationship of preschool special education outcomes to instructional practices and parent-child interaction. *Res Dev Disabil* 2004; 25(6):539-58.

Abstract: Developmental outcomes attained by children receiving preschool special education services in relationship to both the general instructional approach used by their teachers and their parents' style of interaction were examined. The sample included 70 children from 41 Early Childhood Special Education (ECSE) classrooms. The type of instructional model children received was determined by dividing the sample into three clusters based upon six global ratings of children's classroom environment: Choice; Cognitive Problem-Solving; Child-Initiated Learning; Developmental Match; Child-Centered Routines; and Rewards and Discipline Strategies. Based on this analysis, 27 children were classified as receiving developmental instruction; 15 didactic instruction; and 28 naturalistic instruction. Observations of parent-child interaction collected at the beginning and end of the year were classified along four dimensions using the Maternal Behavior Rating Scale: Responsiveness, Affect, Achievement Orientation and Directiveness. Results indicated that the kinds of experiences that children received varied significantly across the three instructional models. However, there were no significant differences in the impact of these instructional models on children's rate of development. Regression analyses indicated that children's rate of development at the end of intervention was significantly related to their parents' style of interaction but was unrelated to the type of instructional model they received.

Maida AM, Molina ME, Erazo R. [Munchausen syndrome by proxy, an unusual presentation]. *Rev Med Chil* 2001; 129(8):917-20.  
Abstract: We report a 12 year old girl that first consulted for fever with bilateral knee arthralgias. A neurological workout was started due to a progressive

gait disturbance, but all results were incongruent with nerve or nerve root lesions, leading to the diagnosis of a functional paralysis. The patient worsened to the point of prostration. Due to the suspicion that the mother was inducing the symptoms, the patient was admitted to the hospital, where she improved notably. She was discharged walking. The improvement during hospital stay confirmed the diagnosis of a Munchausen by proxy syndrome, mimicking a disabling neurological condition.

Major EF. [Treatment of psychologically traumatised patients in Norway]. *Tidsskr Nor Laegeforen* 2003; 123(19):2709-12.

Abstract: **BACKGROUND:** The Norwegian Directorate of Health and Social Affairs is carrying out a project on various aspects of traumatic stress. The present survey was carried out in 2001 in order to gather more knowledge about these patients within the mental health care system. **MATERIAL AND METHODS:** 325 hospitals, outpatient clinics and district psychiatric centres were asked by questionnaire to comment on the types of traumatised patients they treated, their own perceived professional skills, the diagnoses they used and the therapy they offered, and their contact with national and regional specialist units. **RESULTS:** Refugees and victims of sexual abuse were the groups treated by most units; only a few treated veterans of UN/NATO peacekeeping forces. Half of the units reported lack of professional skills in treating refugees. Only a few units reported changes in diagnosis and treatment as a result of advice from the specialist units. **INTERPRETATION:** The high frequency of units reporting a need for better skills in treating refugees is a challenge to the mental health care system and the specialist units. The results suggest a need for discussion of the role of the national and regional specialist units as well as a need for closer cooperation between psychiatric and primary health care.

Malamuth N, Huppin M. Pornography and teenagers: the importance of individual differences. *Adolesc Med Clin* 2005; 16(2):315-26, viii. Abstract: This article focuses on the effects of exposure to pornography on teenagers, particularly males, and concentrates on sexually aggressive outcomes and on the characteristics of the individual as crucial in

determining whether pornography consumption may or may not lead to sexually aggressive outcomes. In future work, it is important not to use an overly simplistic lens of focus in which pornography exposure is seen as generally harmful or not. Depending on particular constellations of personality characteristics, the effects of pornography may differ considerably among different teenagers as well as within different cultures. The research suggests that particular concerns may be needed for those who are highly frequent consumers of pornography, those who seek out sexually violent content, and those who also have other risk factors.

Malcoe LH, Duran BM, Montgomery JM. Socioeconomic disparities in intimate partner violence against Native American women: a cross-sectional study. *BMC Med* 2004; 2:20.

Abstract: **BACKGROUND:** Intimate partner violence (IPV) against women is a global public health problem, yet data on IPV against Native American women are extremely limited. We conducted a cross-sectional study of Native American women to determine prevalence of lifetime and past-year IPV and partner injury; examine IPV in relation to pregnancy; and assess demographic and socioeconomic correlates of past-year IPV. **METHODS:** Participants were recruited from a tribally-operated clinic serving low-income pregnant and childbearing women in southwest Oklahoma. A self-administered survey was completed by 312 Native American women (96% response rate) attending the clinic from June through August 1997. Lifetime and past-year IPV were measured using modified 18-item Conflict Tactics Scales. A socioeconomic index was created based on partner's education, public assistance receipt, and poverty level. **RESULTS:** More than half (58.7%) of participants reported lifetime physical and/or sexual IPV; 39.1% experienced severe physical IPV; 12.2% reported partner-forced sexual activity; and 40.1% reported lifetime partner-perpetrated injuries. A total of 273 women had a spouse or boyfriend during the previous 12 months (although all participants were Native American, 59.0% of partners were non-Native). Among these women, past-year prevalence was 30.1% for physical and/or sexual IPV; 15.8% for severe physical IPV; 3.3% for forced partner-perpetrated sexual activity; and 16.4% for intimate partner injury. Reported IPV prevalence during pregnancy was 9.3%. Pregnancy was not associated with past-year IPV (odds ratio = 0.9). Past-year IPV prevalence was 42.8% among women scoring low on the socioeconomic index, compared with 10.1% among the reference group. After adjusting for age, relationship status, and household size, low socioeconomic index remained strongly associated with past-year IPV (odds ratio = 5.0; 95% confidence interval: 2.4, 10.7). **CONCLUSIONS:** Native American women in our sample experienced exceptionally high rates of lifetime and past-year IPV. Additionally, within this low-income sample, there was strong evidence of

socioeconomic variability in IPV. Further research should determine prevalence of IPV against Native American women from diverse tribes and regions, and examine pathways through which socioeconomic disadvantage may increase their IPV risk.

Mallett RB. Teledermatology in practice. *Clin Exp Dermatol* 2003; 28(4):356-9.  
Abstract: Teledermatology has been the focus of much interest in recent years. Potential uses include a simple supporting role for primary care, more accurate triage of dermatology patients or an 'advice only' service reducing the need for dermatology patients to attend outpatient clinics. With the current under-provision of dermatology services in the UK and the waiting list targets set by government, teledermatology systems have been proposed as a possible solution. 'Store and forward' teledermatology systems are easy to set up and it has been shown that accurate diagnoses can be made using digital images attached to an E-mailed history. In an area of geographical isolation a store and forward teledermatology system has been used successfully to reduce patient waiting times. In Peterborough we have been using a store and forward teledermatology system for over 4 years. Our experience has demonstrated that for only a small number of selected patients was it possible to provide an advice-only service, but the majority of patients still need to be seen in the outpatient clinic. Despite the technical simplicity of these systems today there is still little evidence that teledermatology will have a significant impact on patient workload in the average dermatology clinic. It must be recognized that teledermatology is potentially a useful communication tool for selected patients in primary care but is unlikely to solve waiting list problems or replace the need for local dermatology services.

Malmstrom PM. A regional approach to promoting improved care of multiples. *Twin Res* 2001; 4(2):67-70.  
Abstract: Live births of multiples in the U.S. rose 35% from 87,700 in 1988 to 118,295 in 1998. This increase presents public health issues due to the elevated health and psychosocial risks that accompany multiple birth. However, health and social service providers and educators are poorly prepared to address the specific needs of the multiple birth population. The Twin Service Network Project therefore developed regional networks of multiple birth training and resources in California to address this problem. Results indicate that these can substantially improve the care available to

multiples. The project's integrated package of training and parenting education materials is available to other regions to assist in such efforts.

Malone RE. Tobacco industry surveillance of public health groups: the case of STAT (Stop Teenage Addiction to Tobacco) and INFACT (Infant Formula Action Coalition). *Am J Public Health* 2002; 92(6):955-60.  
Abstract: OBJECTIVES: The goal of this study was to describe how the tobacco industry collects information about public health groups. METHODS: Publicly available internal tobacco industry documents were reviewed and analyzed using a chronological case study approach. RESULTS: The industry engaged in aggressive intelligence gathering, used intermediaries to obtain materials under false pretenses, sent public relations spies to the organizations' meetings, and covertly taped strategy sessions. Other industry strategies included publicly minimizing the effects of boycotts, painting health advocates as "extreme," identifying and exploiting disagreements, and planning to "redirect the funding" of tobacco control organizations to other purposes. CONCLUSIONS: Public health advocates often make light of tobacco industry observers, but industry surveillance may be real, intense, and covert and may obstruct public health initiatives.

Maloni JA, Albrecht SA, Thomas KK, Halleran J, Jones R. Implementing evidence-based practice: reducing risk for low birth weight through pregnancy smoking cessation. *J Obstet Gynecol Neonatal Nurs* 2003; 32(5):676-82.  
Abstract: In 1989, the Association of Women's Health, Obstetric and Neonatal Nurses (AWHONN) developed a research utilization program to integrate evidence into practice areas where there were large discrepancies between research evidence and clinical practice. The current program, renamed Research-Based Practice (RBP), uses translational research methods to build from evidence such as that in the Cochrane database and to create protocols for integration of research directly into clinical practice. This article describes the development of the sixth project (RBP6), in which an evidence-based protocol to address smoking in pregnancy was integrated into clinical practice. The protocol includes screening women using descriptive statements and integrates the 5 As (ask, advise, assess, assist, arrange) into prenatal and postpartum care at every visit. By integrating smoking cessation counseling into care, nurses may reduce the risk of low birth weight among pregnant women in both the United States and Canada.

Mancuso CE, Tanzi MG, Gabay M. Paradoxical reactions to benzodiazepines: literature review and treatment options. *Pharmacotherapy* 2004; 24(9):1177-85.  
Abstract: Benzodiazepines frequently are administered to patients to induce sedation. Paradoxical reactions to

benzodiazepines, characterized by increased talkativeness, emotional release, excitement, and excessive movement, are relatively uncommon and occur in less than 1% of patients. The exact mechanism of paradoxical reactions remains unclear. Most cases are idiosyncratic; however, some evidence suggests that these reactions may occur secondary to a genetic link, history of alcohol abuse, or psychological disturbances. This review evaluates the numerous cases of paradoxical reactions to benzodiazepines in adult and pediatric patients that have been reported in the biomedical literature. It also explores the advantages and disadvantages of the various available treatment options.

Mandich AD, Polatajko HJ, Rodger S. Rites of passage: understanding participation of children with developmental coordination disorder. *Hum Mov Sci* 2003; 22(4-5):583-95.  
Abstract: Children with developmental coordination disorder (DCD) experience difficulty participating in the typical activities of childhood and are known to have a more sedentary pattern of activities than their peers. Little research has been done to investigate the impact of these deficits on the lives of children with DCD and the importance of their participation in the typical activities of childhood. This qualitative study explored the impact of the disorder and the importance of participation for children with DCD from the perspective of the parent. Twelve in-depth interviews were conducted with parents of children with DCD who attended a university clinic specializing in using the Cognitive Orientation to daily Occupational Performance (CO-OP) approach, a cognitive-based intervention. Findings revealed that incompetence in everyday activities had serious negative effects for the children. Conversely, intervention that was focused on enablement at the activity and participation level had a significant positive impact on the children's quality of life. Emerging themes highlighted the notion that performance competency played an important role in being accepted by peers and being able "to be part of the group". As well, parents reported that successful participation built confidence in their children and allowed them to try other new activities. The World Health Organization's International Classification of Functioning, Disability, and Health provides a unique framework for analyzing and understanding the impact of the physical disability on the lives of families with children with DCD. Results illustrate how intervention that focuses on enabling children to choose their own functional goals in the area of physical activity has important implications for enabling participation and

building the social networks of children with DCD.

Mandl KD, Feit S, Larson C, Kohane IS. Newborn screening program practices in the United States: notification, research, and consent. *Pediatrics* 2002; 109(2):269-73.  
Abstract: OBJECTIVE: To define current practice among US newborn screening programs for notification of results, research, and consenting procedures. METHODS: A telephone survey of all US newborn screening program supervisors. RESULTS: All 51 programs participated. All states reported abnormal results to the infant's physician, and some also reported to the hospital and parents. Cases with abnormal results were tracked to different endpoints but usually (92.1%) at least until a follow-up appointment was made. A total of 66.6% of programs can communicate with programs in other states; 9.8% enable families to suppress reporting of results to the infant's physician. No state has a mechanism for parents to prevent results from entering the medical record. Parents or physicians who request results are often authenticated by providing their name (52.9%). Many programs (45.1%) report only to physicians and require just their name (43.5%), an identification number (17.4%), a letter (26.1%), or a parent's signature (26.1%). A total of 70.6% retain residual blood samples; of these, only 8.3% store them completely devoid of patient identifiers. A total of 49.0% of programs aggregate data for research. In 16.0% of these, the data are publicly available. In 24.0%, researchers obtain approval at their own institution; in 24.0%, researchers obtain approval through the state laboratory Institutional Review Board. In 74.5% of programs, parents are notified but not asked for consent before collection of the sample; 19.6% neither notify parents nor obtain consent before screening. CONCLUSIONS: There is wide variation in practice among the US newborn screening programs. Because the programs collectively manage a comprehensive nationwide genomic databank, careful consideration of how information technology and high-throughput genomic analysis are used will be essential to allow progress in clinical care, public health, and research while protecting individual privacy.

Mandlawitz MR. The impact of the legal system on educational programming for young children with autism spectrum disorder. *J Autism Dev Disord* 2002; 32(5):495-508.

Abstract: Since 1990, State Educational Agency (SEA) and Local Educational Agency (LEA) policies and practices of educational programming for young children with autism have evolved in response to the due process system and court decisions. This has become an issue because of an increase in the identification of children with autism, reclassification of children previously reported under other disability categories, publicity about the competition between methodologies, parent advocacy for specific methodologies, shortages of qualified personnel, and

the demand for due process to ensure appropriate services. A review is made of substantive and procedural issues presented in due process and court cases, the legal standards used by hearing officers and judges, and a synthesis of the case law. It is recommended that school districts consider legal standards as programs are designed, that programs fit the unique needs of the child, that programs ensure appropriate progress educationally and socially, and that communication between parents and school districts be open and honest so that the due process system is used as the last resort.

Mani S, Cooper GF. Causal discovery using a Bayesian local causal discovery algorithm. *Medinfo* 2004; 11(Pt 1):731-5.

Abstract: This study focused on the development and application of an efficient algorithm to induce causal relationships from observational data. The algorithm, called BLCD, is based on a causal Bayesian network framework. BLCD initially uses heuristic greedy search to derive the Markov Blanket (MB) of a node that serves as the "locality" for the identification of pair-wise causal relationships. BLCD takes as input a dataset and outputs potential causes of the form variable X causally influences variable Y. Identification of the causal factors of diseases and outcomes, can help formulate better management, prevention and control strategies for the improvement of health care. In this study we focused on investigating factors that may contribute causally to infant mortality in the United States. We used the U.S. Linked Birth/Infant Death dataset for 1991 with more than four million records and about 200 variables for each record. Our sample consisted of 41,155 records randomly selected from the whole dataset. Each record had maternal, paternal and child factors and the outcome at the end of the first year--whether the infant survived or not. Using the infant birth and death dataset as input, BLCD out-put six purported causal relationships. Three out of the six relationships seem plausible. Even though we have not yet discovered a clinically novel causal link, we plan to look for novel causal pathways using the full sample.

Manly JT. Advances in research definitions of child maltreatment. *Child Abuse Negl* 2005; 29(5):425-39.

Manly T, Anderson V, Nimmo-Smith I, Turner A, Watson P, Robertson IH. The differential assessment of children's attention: the Test of Everyday Attention for Children (TEA-Ch), normative sample and ADHD performance. *J Child Psychol Psychiatry* 2001; 42(8):1065-81.

Abstract: "Attention" is not a unitary brain process. Evidence from adult studies indicates that distinct neuroanatomical networks perform specific attentional operations and that these are vulnerable to selective damage. Accordingly, characterising attentional

disorders requires the use of a variety of tasks that differentially challenge these systems. Here we describe a novel battery, the Test of Everyday Attention for Children (TEA-Ch), comprising nine subtests adapted from the adult literature. The performance of 293 healthy children between the ages of 6 and 16 is described together with the relationships to IQ, existing measures of attention, and scholastic attainment. This large normative sample also allows us to test the fit of the adult model of functionally separable attention systems to the observed patterns of variance in children's performance. A Structural Equation Modelling approach supports this view. A three-factor model of sustained and selective attention and higher-level "executive" control formed a good fit to the data, even in the youngest children. A single factor model was rejected. There are behavioural and anatomical grounds to believe that Attention Deficit Disorder (ADD) is particularly associated with poor self-sustained attention and behavioural control. The TEA-Ch performance of 24 boys diagnosed with ADD presented here is consistent with this view. When performance levels on WISC-III subtests were taken into account, specific deficits in sustained attention were apparent while selective attention performance was within the normal range.

Mannes M, Roehlkepartain EC, Benson PL. Unleashing the power of community to strengthen the well-being of children, youth, and families: an asset-building approach. *Child Welfare* 2005; 84(2):233-50. Abstract: Search Institute's decade-plus emphasis on the elements of positive human development and community approaches to asset building can make a meaningful contribution to the field of child welfare. The institute's framework of developmental assets identifies a set of interrelated experiences, relationships, skills, and values that are associated with reduced high-risk behaviors and increased thriving behaviors. Its community-building work emphasizes the human relations and developmental infrastructure children, youth, and families require for their health and well-being.

Mansky PJ, Liewehr DJ, Steinberg SM *et al.* Treatment of metastatic osteosarcoma with the somatostatin analog OncoLar: significant reduction of insulin-like growth factor-1 serum levels. *J Pediatr Hematol Oncol* 2002; 24(6):440-6.

Abstract: BACKGROUND: Insulin-like growth factor-1 (IGF-1) has been implicated in the growth and/or metastasis of osteosarcoma (OS) and chondrosarcoma based on in vitro and experimental animal studies. STUDY PURPOSE: To determine the degree of growth hormone (GH), IGF-1 axis blockade, toxicities, and antitumor effect of OncoLar (ONC) (Novartis, East Hanover, NJ, U.S.A.) in OS. DESIGN/METHODS: A phase 1 study with ONC enrolled 21 OS patients (median age 19 y) in four cohorts: ONC 60 mg or 90 mg intramuscularly every 4 weeks with/without

tamoxifen (TAM) 20 mg oral daily. RESULTS: There were no dose-limiting toxicities. Nineteen percent of patients had grade III drug-related toxicities including: 62% of patients showed progressive disease after two courses (8 wk). Nineteen percent received four courses. No clinical responses were observed. At weeks two and eight of therapy, IGF-1 serum levels dropped 46% ( $< 0.0001$ ,  $n = 21$ ) and 53% ( $= 0.003$ ,  $n = 10$ ). The difference of the area under the curve (AUC) minus baseline AUC (DeltaAUC) for arginine-stimulated GH serum levels at week two was lower than baseline ( $< 0.01$ ). At weeks two and eight, GH peak values were lower than baseline ( $< 0.0001$  and  $= 0.002$ , respectively). CONCLUSIONS: A long-acting somatostatin analog was able to lower IGF-1 levels of OS patients. IGF-BP-3 and GH were only transiently reduced. Although ONC was well tolerated, no sustained clinical responses were observed. The pathophysiology of serum versus tissue concentrations of IGF-1 as well as the interplay of IGFs, IGF-binding proteins, and other growth factors and cytokines in osteosarcoma warrants further investigation. A better understanding of these processes should lead to a more effective exploitation of these pathways for the targeted therapy of OS.

Manwell LB, Czabala JC, Ignaczak M, Mundt MP. Correlates of depression among heavy drinkers in Polish primary care clinics. *Int J Psychiatry Med* 2004; 34(2):165-78.  
Abstract: OBJECTIVE: Depression and co-morbid substance abuse disorders are a major public health problem. Information is limited for patients attending Polish primary care clinics. This article addresses 30-day and lifetime prevalence of major depression in a heavy drinking population from 12 Polish primary care clinics. METHOD: 277 heavy drinkers were interviewed by a researcher in each clinic. Heavy drinking was defined as more than 20 drinks per week for males, or more than 13 drinks per week for females, or consumption of more than four drinks five or more times in the previous 30 days, or two or more positive replies to the CAGE questions. Criteria from the Diagnostic and Statistical Manual were used to assess lifetime and past 30-day depression. RESULTS: 35% of women and men met criteria for depression in the 30 days prior to the interview. Lifetime rates were 45% for women and 52% for men. Men and women with a CAGE score of 4 were at higher risk for both 30-day (67%, OR = 3.85 [1.47, 10.08]) and lifetime (78%, OR = 3.28 [1.12, 9.66]) depression. Recreational drug users and patients reporting symptoms of anti-social personality disorders were at increased risk for lifetime depression. Subjects reporting symptoms of a childhood conduct disorder were at higher risk for 30-day depression. CONCLUSIONS: Depression among patients with substance abuse problems is a common problem. The rates are higher than for other countries and highlight the need for Polish primary care clinicians to routinely screen for depression in patients

with substance use disorders.

Marais S, Kritzinger A. Farm worker injuries on Western Cape fruit farms: the role of the lay health worker. *Curationis* 2005; 28(4):86-92.  
Abstract: AIM AND METHOD: An exploratory and descriptive study to obtain basic data on the extent, nature, sources and severity of injuries sustained on fruit farms was conducted. The possibility of utilizing lay health workers (LHWs) on farms to document routine information on injuries was also investigated. Descriptive information of all injuries occurring on selected farms, both occupational and other, needing some form of treatment, were documented over a one-year period from June 1999 to May 2000. A purposive non-probability sampling method was used. Forty-eight fruit farms with a history of trained LHWs were purposefully selected. Injuries were documented using a one-page questionnaire. RESULTS: A total of 500 injuries were recorded, giving an average of 10.4 injuries per farm per year. Half of these injuries were work-related. Workers aged 20-39 were most at risk. Injuries sustained were related to routine activities of fruit farming, occurred mostly in the orchards and involved cuts, bruises and abrasions to the hands, including the fingers, and the eyes. Most of the non-work related injuries occurred in and around the home. A third of these injuries were sustained by persons  $< 20$ . A large percentage of the non-work related injuries were violence- and alcohol related. Most of the injuries required basic primary health care that could be managed by the LHW. Injury severity caused people to take time off for one third of the cases. CONCLUSION: A relatively high occupational injury rate in comparison to high-income countries. Occupational Health and Safety legislation needs to be institutionalized and adhered to. Alcohol and violence on farms is a serious public health problem. LHWs could potentially play an important role in documenting injury data.

Maranan P. Training community members for action: Washington's Action Training Network. *J Health Hum Serv Adm* 2002; 24(4):413-30.  
Abstract: The Children's Alliance in Washington State has established an ambitious goal of building the "Children's Action Network" (Network), a statewide network of children's advocates who regularly take action to inform public policy related to children and families. There are currently about 3,000 members in the Network. Policy advocacy training is an integral component of the Network providing advocates with necessary tips and tools for communicating with policy-makers. In order to meet key objectives and overcome significant challenges and barriers, the training program evolved greatly over the last five years. This article describes some of the challenges faced, particularly in reaching specific target populations, key strategies undertaken, and how the curriculum developed over time.

Marcovitch H. Learning from tragedies: clinical lessons from the Climbe report. *Qual Saf Health Care* 2003; 12(2):82-3.

Margolina IA, Kozlovskaia GV, Proselkova ME. [Mental development of children in condition of chronic physical abuse: methodical aspect]. *Zh Nevrol Psikhiatr Im S S Korsakova* 2005; 105(9):4-9. Abstract: Mental dysfunction of 130 children aged 0-14 years with a history of family physical abuse was studied using a number of known methods adapted for early aged children including an original scale of mental dysfunction assessment, which has been elaborated in Mental Health Research Center (Moscow). A battery of clinico-psychopathological and clinico-psychological methods allowed comprehensive assessment of mental state, with 95% cases of mental dysfunction being found in the group studied. The most pronounced were depression spectrum disorders.

Marino R, Villa A, Guerrero S. A community trial of fluoridated powdered milk in Chile. *Community Dent Oral Epidemiol* 2001; 29(6):435-42. Abstract: OBJECTIVE: To demonstrate the effectiveness of a dental caries prevention program on the primary dentition of Chilean rural children, using fluoridated powdered milk and milk derivatives. METHODS: Fluoridated milk and milk-cereal was given to about 1000 preschool children in Codegua, a rural community located in the 6th Region of Chile, using the standard National Complementary Feeding Program (PNAC). The daily fluoride dose from fluoridated powdered milk was estimated at 0.25 mg for infants (0-2 years old), 0.5 mg for children aged 2-3 years and 0.75 for children aged 3-6 years. Cross-sectional samples of children aged 3-6 years were taken from Codegua (study community) from 1994 to 1999 and from La Punta (control community) from 1997 and 1999. RESULTS: Significant reductions (72%) were observed in the dmfs indices in the 3-6-year-old groups in Codegua, when comparing 1999 with 1994 data. In 1999, children in the study community showed significantly lower dmfs than children in the control community (41%). The proportion of caries-free children in the study community increased after 4 years of program implementation (from 22.0% to 48.4%). CONCLUSION: Under Chilean rural conditions, fluoridation of powdered milk distributed through the PNAC is an effective caries prevention alternative for areas where water fluoridation might not be feasible.

Marks DJ, Berwid OG, Santra A, Kera EC, Cyrulnik SE, Halperin JM. Neuropsychological correlates of ADHD symptoms in preschoolers. *Neuropsychology* 2005; 19(4):446-55.

Abstract: The authors examined the neuropsychological status of 22 preschoolers at risk for attention-deficit/hyperactivity disorder (ADHD) and 50 matched control children, using measures of nonverbal working memory, perceptual and motor inhibition, and memory for relative time. All tasks included paired control conditions, which allowed for the isolation of discrete executive function constructs. Group differences were evident on several measures of neuropsychological functioning; however, after accounting for nonexecutive abilities, no deficits could be attributed to specific functions targeted by the tasks. Performance on executive measures was not related to objective indices of activity level or ratings of ADHD symptoms. Yet, the fact that at-risk preschoolers were highly symptomatic casts doubt on whether executive function deficits and/or frontostriatal networks contribute etiologically to early behavioral manifestations of ADHD.

Marks L. Sacred practices in highly religious families: Christian, Jewish, Mormon, and Muslim perspectives. *Fam Process* 2004; 43(2):217-31. Abstract: Quantitative research examining linkages between family relationships and religious experience has increased substantially in recent years. However, related qualitative research, including research that examines the processes and meanings behind recurring religion-family correlations, remains scant. To address this paucity, a racially diverse sample (N = 24) of married, highly religious Christian, Jewish, Mormon, and Muslim parents of school-aged children were interviewed regarding the importance of religious family interactions, rituals, and practices in their families. Mothers and fathers discussed several religious practices that were meaningful to them and explained why these practices were meaningful. Parents also identified costs and challenges associated with these practices. Interview data are presented in connection with three themes: (1) "practicing [and parenting] what you preach," (2) religious practices, family connection, and family communion, and (3) costs of family religious practices. The importance of family clinicians and researchers attending to the influence of religious practice in the lives of highly religious individuals and families is discussed.

Marks MB, Lawson HA. Co-production dynamics and time dollar programs in community-based child welfare initiatives for hard-to-serve youth and families. *Child Welfare* 2005; 84(2):209-32. Abstract: Hard-to-serve youth and families residing in high-poverty communities often have multiple, interlocking needs. These needs necessitate complex service models. The complex model described in this article combines a unique approach to wraparound services with a coproduction framework and related theories. The model aims to improve outcomes for vulnerable youth and their families, simultaneously strengthening communities by employing residents and

engaging participants in community service. Examples derived from current pilot projects illustrate co-production's importance for other child welfare initiatives.

Marleau JD. Birth order and fratricide: an evaluation of Sulloway's hypothesis. *Med Sci Law* 2005; 45(1):52-6. Abstract: Sulloway (1996) suggested that older siblings were more likely to be fratricidal than younger ones. Our data, based on 113 case studies found in the psychiatric, psychological and criminological literature since 1959, confirms his hypothesis. In 72 out of the 92 cases (78%) where age could be determined, the aggressor was older than the victim. The same held true even when the age of aggressor, sex of aggressor and victim, presence or not of a blood tie, and presence of one or more victims are taken into account. Surprisingly, most of the aggressors in our sample were under the age of 18 years. Also, first-borns were more often the aggressor than the victim. This result seems to confirm the Adlerian theory of dethronement. Some suggestions and hypotheses are advanced for future research to improve our understanding of this phenomenon.

Marley JA, Buila S. Crimes against people with mental illness: types, perpetrators, and influencing factors. *Soc Work* 2001; 46(2):115-24. Abstract: The current emphasis on studying why people with severe mental illness are potentially violent has overlooked the effect of violence committed against these individuals. To balance the understanding of the person-in-environment conceptualization of severe mental illness, the nature, scope, and effect of crime and victimization should be examined as part of the context in which these individuals live and function. The study reported in this article examined the nature and scope of victimization as experienced by 234 individuals with a diagnosed major mental illness; what types of victimization experiences occurred during their lifetime; what specific victimization experiences these individuals identified as the most troubling; who the perpetrators for these specific victimization experiences were; and what influence demographic and clinical characteristics played in influencing the risk of victimization among this group. The study indicates that social workers should better assess for experiences of victimization among people with mental illness and better understand the effect of such experiences on the individual's symptoms and day-to-day functioning.

Maroteaux P, Le Merrer M. [Battered or brittle child?]. *Arch Pediatr* 2003; 10(8):679-80.

Marquardt RK, Levitt JG, Blanton RE *et al.* Abnormal development of the anterior cingulate in childhood-onset schizophrenia: a preliminary quantitative MRI study. *Psychiatry Res* 2005; 138(3):221-33.

Abstract: The anterior cingulate is a key component of neural networks subserving attention and emotion regulation, functions often impaired in patients with psychosis. The study aimed to examine anterior cingulate volumes and sulcal morphology in a group of patients with childhood-onset schizophrenia (COS) compared with controls. Brain magnetic resonance imaging (MRI) scans were obtained in 13 COS and 18 matched control children, ages 6-17 years. Volume measures for the anterior cingulate gyrus (ACG) were obtained through manual labeling. A determination of cingulate sulcal pattern (single or double) was made for each hemisphere. The COS group had a reduced leftward skew of the double cingulate sulcal pattern, and absence of the normal left>right ACG volume asymmetry. The right ACG was larger in the COS than in controls. The schizophrenic children showed decreases in all ACG volumes with age, while the controls showed increases or no change. The data suggest that significant cingulate abnormalities may result from deviations in progressive neurodevelopmental processes, beginning before birth and continuing through childhood and adolescence, in persons who develop schizophrenia. These structural differences may relate to the well-described cognitive deficits these children display, and to the cardinal symptoms of schizophrenia.

Marques NM, Lira PI, Lima MC *et al.* Breastfeeding and early weaning practices in northeast Brazil: a longitudinal study. *Pediatrics* 2001; 108(4):E66. Abstract: OBJECTIVES: To describe breastfeeding practices from 0 to 12 months of age in 4 small towns that are representative of urban northeast Brazil and to identify factors associated with introduction of other milk in the first month of life. METHODS: From January to August 1998, 364 mothers were interviewed at delivery to ascertain antenatal care; delivery room practices; and their intentions regarding breastfeeding, pacifiers, and introduction of water, teas, and other milk. Their perceptions of home support and the advantages of breastfeeding also were assessed. Thereafter, daily information about feeding practices was collected at twice-weekly home visits. When other milk was started, a second interview was conducted to ascertain initial and current breastfeeding problems and use of a pacifier. Reasons for starting other milk were investigated using 5-point Likert scales. RESULTS: Mothers were positive toward breastfeeding, and 99% breastfed their new infant. Few intended to breastfeed exclusively, and in the first week 80% gave water/tea and 56% used a pacifier. The median duration of exclusive breastfeeding was 0 days, and the median age for starting other milk was 24 days. The median duration of breastfeeding was 65 days for mothers who started other milk within 1 month and 165 days for other mothers. After adjustment for confounding variables, the main factors associated with introduction of other milk within 1 month were pacifier use in the first week (odds ratio [OR], 4.01; 95% confidence

- interval [CI]: 2.07-7.78), intention to start other milk in the first month (OR, 3.79; 95% CI: 1.74-8.24), giving water/tea in the first week (OR, 3.07; 95% CI: 1.56-6.03), and leaving the maternity ward before breastfeeding was started (OR, 2.59; 95% CI: 1.34-5.04). CONCLUSION: Although breastfeeding is common in this community, it rarely is exclusive and takes place for a relatively short duration. Identification of risk factors for early introduction of other milk offers potential avenues for future intervention, including improvement of breastfeeding support in antenatal and maternity services.
- Marsella LT, Savastano L, Saracino V, Del Vecchio R. [Child labour]. *Clin Ter* 2005; 156(6):273-80. Abstract: The authors emphasize the violation of children's and adolescents' rights as a result of the exploitation of child labour. Besides the legal aspect, they pointed out the medical features related to the delicate growing process of the child in the phases of development and adaptation of the main organs to hard work. Currently the problem is being supervised by those states that recognize the right for minors to be protected against any kind of physical, mental, spiritual and moral risk.

- Martin MA, Rubio JC, Buchbinder J *et al*. Molecular heterogeneity of myophosphorylase deficiency (McArdle's disease): a genotype-phenotype correlation study. *Ann Neurol* 2001; 50(5):574-81. Abstract: We report on 54 Spanish patients with McArdle's disease from 40 unrelated families. Molecular analysis revealed that the most common R49X mutation was present in 70% of patients and 55% of alleles. The G204S mutation was less frequent and found in 14.8% of patients and 9% of mutant alleles. The W797R mutation was observed in 16.5% of patients, accounting for 13.7% of mutant alleles. Moreover, 78% of mutant alleles among Spanish patients can be identified by using polymerase chain reaction-restriction fragment length polymorphism analysis for the R49X, G204S, and W797R mutations, which makes noninvasive diagnosis possible through molecular genetic analysis of blood DNA. Six novel mutations were found. Three were missense mutations, E348K, R601W, and A703V; two nonsense mutations, E124X and Q754X; and one single base pair deletion, 533 delA. No clear genotype-phenotype correlation emerges from our study. Most of the mutations of uncharged and solvent inaccessible residues and the truncations must disrupt the basic structure of the protein. The mutations of charged residues would be expected to interfere with internal hydrogen bonding networks, introducing severe incompatible partnering that is caused by poor packing or electrostatic repulsions.
- Martin PL. Moving toward an international standard in informed consent: the impact of intersexuality and the Internet on the standard of care. *Duke J Gend Law Policy* 2002; 9:135-69. Notes: GENERAL NOTE: KIE: 310 fn. GENERAL NOTE: KIE: KIE Bib: informed consent/minors; patient care/minors
- Martin SG. Children exposed to domestic violence: psychological considerations for health care practitioners. *Holist Nurs Pract* 2002; 16(3):7-15. Abstract: This article reviews the psychological impact of exposure to domestic violence on child development. The purpose is to give insight to the following questions: How does the experience of family violence affect a child's perception of the world and relationships with others? What type of coping style might this same child be likely to develop? What factors help protect a child who has been exposed to violence in the home? In addition, the article discusses assessment considerations for health care practitioners and recommends areas for future research and public policy development.
- Martin SL, Mackie L, Kupper LL, Buescher PA, Moracco KE. Physical abuse of women before, during, and after pregnancy. *JAMA* 2001; 285(12):1581-4. Abstract: CONTEXT: Clinicians who care for new mothers and infants need information concerning postpartum physical abuse of women as a foundation on which to develop appropriate clinical screening and intervention procedures. However, no previous population-based studies have been conducted of postpartum physical abuse. OBJECTIVES: To examine patterns of physical abuse before, during, and after pregnancy in a representative statewide sample of North Carolina women. DESIGN, SETTING, AND PARTICIPANTS: Survey of participants in the North Carolina Pregnancy Risk Assessment Monitoring System (NC PRAMS). Of the 3542 women invited to participate in NC PRAMS between July 1, 1997, and December 31, 1998, 75% (n = 2648) responded. MAIN OUTCOME MEASURES: Prevalence of physical abuse during the 12 months before pregnancy, during pregnancy, and after infant delivery; injuries and medical interventions resulting from postpartum abuse; and patterns of abuse over time in relation to sociodemographic characteristics and use of well-baby care. RESULTS: The prevalence of abuse before pregnancy was 6.9% (95% confidence interval [CI],

5.6%-8.2%) compared with 6.1% (95% CI, 4.8%-7.4%) during pregnancy and 3.2% (95% CI, 2.3%-4.1%) during a mean postpartum period of 3.6 months. Abuse during a previous period was strongly predictive of later abuse. Most women who were abused after pregnancy (77%) were injured, but only 23% received medical treatment for their injuries. Virtually all abused and nonabused women used well-baby care; private physicians were the most common source of care. The mean number of well-baby care visits did not differ significantly by maternal patterns of abuse. CONCLUSION: Since well-baby care use is similar for abused and nonabused mothers, pediatric practices may be important settings for screening women for violence.

Martines J, Paul VK, Bhutta ZA *et al.* Neonatal survival: a call for action. *Lancet* 2005; 365(9465):1189-97. Notes: CORPORATE NAME: Lancet Neonatal Survival Steering Team  
Abstract: To achieve the Millennium Development Goal for child survival (MDG-4), neonatal deaths need to be prevented. Previous papers in this series have presented the size of the problem, discussed cost-effective interventions, and outlined a systematic approach to overcoming health-system constraints to scaling up. We address issues related to improving neonatal survival. Countries should not wait to initiate action. Success is possible in low-income countries and without highly developed technology. Effective, low-cost interventions exist, but are not present in programmes. Specific efforts are needed by safe motherhood and child survival programmes. Improved availability of skilled care during childbirth and family/community-based care through postnatal home visits will benefit mothers and their newborn babies. Incorporation of management of neonatal illness into the integrated management of childhood illness initiative (IMCI) will improve child survival. Engagement of the community and promotion of demand for care are crucial. To halve neonatal mortality between 2000 and 2015 should be one of the targets of MDG-4. Development, implementation, and monitoring of national action plans for neonatal survival is a priority. We estimate the running costs of the selected packages at 90% coverage in the 75 countries with the highest mortality rates to be US\$4.1 billion dollars a year, in addition to current expenditures of 2.0 billion dollars. About 30% of this money would be for interventions that have specific benefit for the newborn child; the remaining 70% will also benefit mothers and older children, and substantially reduce rates of stillbirths. The cost per neonatal death averted is estimated at 2100 dollars (range 1700-3100 dollars). Maternal, neonatal, and child health receive little funding relative to the large numbers of deaths. International donors and leaders of developing countries should be held accountable for meeting their commitments and increasing resources.

Martinez CR Jr, Forgatch MS. Adjusting to change: linking family structure transitions with parenting and boys' adjustment. *J Fam Psychol* 2002; 16(2):107-17. Abstract: This study examined links between family structure transitions and children's academic, behavioral, and emotional outcomes in a sample of 238 divorcing mothers and their sons in Grades 1-3. Multiple methods and agents were used in assessing family process variables and child outcomes. Findings suggest that greater accumulations of family transitions were associated with poorer academic functioning, greater acting-out behavior, and worse emotional adjustment for boys. However, in all three cases, these relationships were mediated by parenting practices: Parental academic skill encouragement mediated the relationship between transitions and academic functioning, and a factor of more general effective parenting practices mediated the relationships between transitions and acting out and emotional adjustment.

Martinez-Campillo Garcia F, Maura da Fonseca A, Santiago Oliva J *et al.* [Vaccine coverage study and intervention with health community agents in a marginal gypsy community of Alicante]. *Aten Primaria* 2003; 31(4):234-8.

Abstract: OBJETIVOS: To measure the vaccination coverage in a pediatric population living in Parque Ansaldo, Montoto, Casa Larga, Cabrera Vicario, San Anton and Travesia del Canal and evolution after an intervention health program performed by Gypsy educators specially trained for such intervention. DESIGN: Descriptive study, pretest-posttest without control group. SETTING: Community. Primary health care. Participants. Four hundred and sixty three marginals Gypsies children younger than 15 years old. MEASUREMENTS AND MAIN RESULTS: The project includes an educational program and health care actions by means of home visits. Duration of the project was from 1-10-96 until 1-10-97 and from 1-10-98 until 1-10-99. Before intervention the vaccine coverage was for polio, diphtheria and tetanus 41%, pertussis 24% and measles, mumps and rubella 36%. After intervention the overall coverage increased 17%. The vaccine coverage was for polio, diphtheria and tetanus 53%, pertussis 45% y measles, mumps and rubella 54%. CONCLUSIONS: This study shows up the low vaccine coverage founded and the increase of overall coverage after the intervention in 17%. We also conclude of the intervention the necessity of collaboration between Gypsies associations, health primary care centers and public health centers to carry out efficacy interventions in marginal population.

Martino SC, Collins RL, Kanouse DE, Elliott M, Berry SH.

Social cognitive processes mediating the relationship between exposure to television's sexual content and adolescents' sexual behavior. *J Pers Soc Psychol* 2005; 89(6):914-24.

Abstract: This study used multiple-group structural equation modeling to test a model explaining the association between exposure to televised sexual content and initiation of intercourse among an ethnically diverse national sample of 1,292 adolescents. The authors hypothesized, on the basis of social-cognitive theory, that exposure to televised sexual content would influence adolescents' safe-sex self-efficacy, sex-related outcome expectancies, and perceived peer norms regarding sex, and that each of these would, in turn, influence intercourse initiation. Findings support a model in which the relationship between exposure to TV's sexual content and intercourse initiation is mediated by safe-sex self-efficacy among African Americans and Whites but not among Hispanics. Outcome expectancies and perceived peer norms may also mediate the link between exposure and intercourse initiation among all 3 racial/ethnic groups, although evidence of this could not be confirmed.

Martins CB, Andrade SM. [Epidemiology of accidents and violence against children in a city of Southern Brazil]. *Rev Lat Am Enfermagem* 2005; 13(4):530-7. Abstract: This study aimed to analyze the epidemiological characteristics of accidents and violence against children under 15 years old who lived in Londrina, a city in the South of Brazil, in 2001. Morbidity data were collected from general hospitals records and mortality data were obtained from the Municipal Mortality Information Center. A total of 8,854 children were studied, which corresponded to an incidence rate of 74.8/1,000 children. Admission and fatality rates were 4.2% and 0.2%, respectively. The incidence rate was higher among two-year olds (109/1,000) and male victims prevailed (60.7%). Other causes of injuries were the main subtype of external cause (61.0%), followed by events of undetermined intention (30.6%) and by transport-related injuries (7.5%). The head was the most affected body part (34.9%) and superficial injuries were the most frequent kind of trauma (32.4%). The results contribute to the planning of injury control and prevention actions.

Martins CS, Ferriani MG. [Reintegration of victimized children and adolescents in their parents' view]. *Rev Bras Enferm* 2003; 56(6):651-4. Abstract: This study aims at learning, from some aggressor families' point of view, the way reintegration of child and adolescent victims into their own families happen, in the city of Ribeirao Preto-SP in 2002. The methodology used is descriptive and qualitative; data were collected through interviews and observation of participants. Nine families whose children were institutionalized were surveyed. Results showed that the institutionalization of children is a way for some

families to rethink the kind of education parents are providing their children with/their own education. For the other ones, it was perceived as a support for behavioral problems. As noticed, some parents stressed a negative influence falling upon their children, which made them more disobedient on their return home, and causing disciplinary procedures harder to be established. The conclusion is that reintegration of the target children/adolescents is harnessed by violence happening inside families.

Masi G, Millepiedi S, Mucci M, Bertini N, Milantoni L, Arcangeli F. A naturalistic study of referred children and adolescents with obsessive-compulsive disorder. *J Am Acad Child Adolesc Psychiatry* 2005; 44(7):673-81.

Abstract: OBJECTIVE: To report on clinical features, comorbidity, and response to pharmacotherapy in children and adolescents with obsessive-compulsive disorder (OCD) naturalistically followed and treated with serotonin reuptake inhibitors (SRIs). METHOD: A consecutive series of 94 patients (65 males, 29 females, age 13.6 +/- 2.8 years), referred in the period January 2001-April 2004, diagnosed with a clinical interview (Diagnostic Interview for Children and Adolescents-Revised), and followed for 10 +/- 6 months, were included in the study. RESULTS: Contamination obsessions and washing rituals were associated with less impairment than other subtypes of OCD. Aggressive sexual obsessions and checking rituals as well as symmetry obsessions and ordering-repeating rituals were more frequently comorbid with tic disorders. According to the Clinical Global Impressions-Improvement scale (score 1 or 2), 63 subjects (67%) were responders to treatment. Nonresponders were more severely impaired and had a higher number of comorbid disorders, namely, bipolar disorder and conduct disorder ( $p < .05$ ). Forty-seven patients (50%) received an SRI monotherapy, whereas the other 47 (50%) needed other medications. Patients receiving SRI monotherapy were less severely impaired; had a later onset of OCD; were at a younger age at the visit, had higher rates of depression and anxiety and lower rates of bipolar disorder, attention-deficit/hyperactivity disorder, and conduct disorder ( $p < .05$ ). CONCLUSIONS: Long-term naturalistic prospective studies in pediatric patients with OCD might represent an important source of information for everyday care regarding the effectiveness of a treatment over extended periods of time under routine clinical conditions.

Mason PR, Gregson S, Gwanzura L, Cappuccinelli P, Rapelli P, Fiori PL. Enzyme immunoassay for urogenital trichomoniasis as a marker of unsafe sexual behaviour. *Epidemiol Infect* 2001; 126(1):103-9.

Abstract: Enzyme immunoassay (EIA) was used to detect antibodies to *Trichomonas vaginalis* in sera from Zimbabwe. The EIA showed a sensitivity of 95 and 94% when compared with vaginal swab culture among women attending a family planning clinic (FPC) and female commercial sex workers (CSW) respectively. The specificity was 85 and 77% in the two groups. Culture-negative FPC women were sub-divided into high risk or low risk of exposure to trichomoniasis. The seroprevalence was 10% (6/61) among low risk women, 21% (10/48) among high risk women and 23% (9/39) among culture negative CSW. The EIA was positive in 46% (18/39) men with genital discharge but only 5% (2/37) healthy blood donors. None of 31 sera from prepubescent children was positive. The EIA may be useful for community surveys of trichomoniasis. Because *T. vaginalis* is a common sexually transmitted disease, the test may indicate behaviour that increases the risk of STD transmission.

Mastroianni AC, Kahn JP. Risk and responsibility: ethics, *Grimes v Kennedy Krieger*, and public health research involving children. *Am J Public Health* 2002; 92(7):1073-6.

Notes: GENERAL NOTE: KIE: 10 refs. GENERAL NOTE: KIE: KIE Bib: human experimentation/informed consent; human experimentation/minors; public health  
Abstract: The legal case of *Grimes v. Kennedy Krieger Institute, Inc*, has raised concerns in the public health research community regarding the acceptable level of risk in research involving children, parental authority for informed consent, and exploitation of research subjects for the benefit of public health. We provide an overview of the case and discuss the impact of the court's decision and its possible effect on future research protection policies and practices.

Mathew SJ, Mao X, Coplan JD *et al.* Dorsolateral prefrontal cortical pathology in generalized anxiety disorder: a proton magnetic resonance spectroscopic imaging study. *Am J Psychiatry* 2004; 161(6):1119-21.  
Abstract: OBJECTIVE: Few neuroimaging studies of generalized anxiety disorder have been conducted. The present study used proton magnetic resonance spectroscopy to assess concentrations of N-acetylaspartate, often considered a marker of neuronal viability, in generalized anxiety disorder patients. METHOD: N-Acetylaspartate/creatine resonance ratios were measured in the left and right dorsolateral prefrontal cortex and hippocampus of 15 medication-free generalized anxiety disorder patients and 15 age- and sex-matched healthy volunteers. RESULTS: Generalized anxiety disorder patients had a 16.5% higher N-acetylaspartate/creatine ratio in the right

dorsolateral prefrontal cortex compared with healthy participants; 13 of 15 matched patient-comparison subject pairs displayed a difference in this direction. In addition, generalized anxiety disorder patients reporting childhood abuse had lower N-acetylaspartate/creatine ratios in the right dorsolateral prefrontal cortex than did nonabused patients. Metabolite differences were not detected in other regions. CONCLUSIONS: Generalized anxiety disorder is associated with asymmetric increases in the N-acetylaspartate/creatine ratio, a suggested marker of neuronal viability, in the prefrontal cortex. The findings also support prior research linking childhood abuse to reduced neuronal viability.

Maton KI, Hrabowski FA 3rd. Increasing the number of African American PhDs in the sciences and engineering: a strengths-based approach. *Am Psychol* 2004; 59(6):547-56.

Abstract: Fifty years after *Brown v. Board of Education*, the percentage of African American students who receive PhDs in natural science, technology, engineering, or mathematics (STEM) fields remains disappointingly low. A multifaceted, strengths-based approach to intervention and research that holds great promise for increasing the number of African American students who achieve at the highest levels academically is described. This work began in 1988 with the development of the Meyerhoff Scholars Program for undergraduate minority STEM majors at the University of Maryland, Baltimore County (UMBC). If current PhD receipt rates of program graduates continue, UMBC will in all likelihood become the leading predominantly White baccalaureate-origin university for Black STEM PhDs in the nation. The program is described and outcome and process findings from its ongoing evaluation are highlighted. The parenting practices that helped these youths to overcome the odds and achieve at the highest levels prior to coming to college are also examined.

Matsuda I. Bioethical considerations in neonatal screening: Japanese experiences. *Southeast Asian J Trop Med Public Health* 2003; 34 Suppl 3:46-8.  
Abstract: Since 1979, at least 13,000 affected babies have been identified with one of the tested diseases. The outcome for patients is generally favorable if adequate treatment is given. Recently, ethical issues have arisen concerning whether or not written informed consent should be required, under what conditions the residual blood spot may be used for research purposes other than that originally designed, and whether or not the test is cost-effective. Mandatory screening seems acceptable under certain conditions, but parental education and opportunity for refusal should be part of the system. Refusal should be documented only after an attempt has been made to persuade parents to consent. Informed consent is necessary if there is uncertainty about the test's benefit to the child. Parents should be informed of the potential research value of

the samples and assured that research results will not be linked to any particular/individual newborn. If identified or coded blood spots are used for research, IRB review and approval by IRB must occur. The net health care benefit from screening for six disorders in Japan was 0.25 billion yen (\$2.2 million) per 100,000 screened newborns compared to \$3.2 million for PKU and CH in the US for 100,000 screened newborns.

Matsumoto T, Yamaguchi A, Asami T, Okada T, Yoshikawa K, Hirayasu Y. Characteristics of self-cutters among male inmates: association with bulimia and dissociation. *Psychiatry Clin Neurosci* 2005; 59(3):319-26.

Abstract: It was examined whether bulimia and dissociation are common in male self-cutters, as has been found in female self-cutters. The subjects were 796 male inmates of a juvenile prison. A self-reporting questionnaire was used to assess self-cutting, histories of psychoactive substance use, problem behaviors, and traumatic life events in the subjects. The Adolescent Dissociative Experience Scale and the Bulimia Investigatory Test of Edinburgh were also used. Subjects were divided into two groups: self-cutting and non-cutting. Questionnaire responses and dissociation and bulimia assessments were compared between the groups. Self-cutters began smoking ( $P < 0.001$ ) and drinking ( $P < 0.001$ ) earlier, and more frequently used illicit psychoactive drugs ( $P < 0.001$ ), experienced childhood physical abuse ( $P < 0.001$ ), and reported suicide attempts ( $P < 0.001$ ), suicidal ideation ( $P < 0.001$ ), and outward violence toward a person ( $P < 0.001$ ) or object ( $P < 0.001$ ) than non-cutters. Self-cutters also scored significantly higher on the bulimia ( $P < 0.001$ ) and dissociation tests ( $P < 0.001$ ). Logistic regression analysis demonstrated that suicide attempt (odds ratio, 4.311) and suicidal ideation (odds ratio, 2.336) could discriminate between male inmates with and without self-cutting. Male self-cutters showed 'multi-impulsive bulimic' tendencies resembling those of female self-cutters, although to a lesser extent. Clinical features of male as opposed to female self-cutters were influenced by gender differences.

Matthys W, Maassen GH, Cuperus JM, van Engeland H. The assessment of the situational specificity of children's problems behaviour in peer-peer context. *J Child Psychol Psychiatry* 2001; 42(3):413-20. Abstract: In both theory and research the general issue of the extent to which children's problem behaviour is generalised across situations, and to what extent it is situation specific, has been neglected. In the clinical assessment of disordered children, too, little attention has been paid to the specific situations in which these children display their inappropriate behaviour. In this study the Taxonomy of Problematic Social Situations (TOPS) (Dodge, McClaskey, & Feldman, 1985) was employed. This is a questionnaire in which the child's teacher is asked to rate the likelihood of a child responding in an inappropriate manner in a specific

situation. Characteristics of TOPS were investigated both in randomly selected normal school children and in boys with a conduct disorder. Four factors appeared to underlie the TOPS scores from 652 randomly selected boys and girls from grades 1 to 6, these being: teachers' scores for the types of problem situation Being Disadvantaged, Coping with Competition, Social Expectations of Peers, and Teacher Expectations. Because of the high internal consistency of the four factors, TOPS was abbreviated to a TOPS-Short Form (18 instead of 44 items). The four-factor model was cross-validated by means of a second sample of 326 boys and girls. A model with only one general problem behaviour factor did not fit the data of both samples. When the four specific factors were added a satisfactory fit resulted. Moreover, it was found that in the first sample 52% of the variance was explained by the general factor, whereas 18% of the variance was explained by the four specific factors together. Thus, the extent to which problem behaviour is situation specific should not be disregarded. In all four types of problem situation, boys showed more inappropriate behaviour than girls. With increasing age, children were rated as being more competent in dealing with the problem situation Being Disadvantaged. Teachers rated the four types of problem situation as more problematic for boys with a conduct disorder ( $N = 42$ ) than for normal control boys ( $N = 67$ ). Conduct disordered boys also differed individually in the number of situational types that were problematic for them. With respect to clinical implications, the identification of the particular social context in which a conduct disordered child displays his or her inappropriate behaviour may help refine treatment goals: more adequate social functioning should be aimed at specifically in those situations that are problematic.

Maughan B, Iervolino AC, Collishaw S. Time trends in child and adolescent mental disorders. *Curr Opin Psychiatry* 2005; 18(4):381-5.

Abstract: PURPOSE OF REVIEW: 1995 saw the publication of a major review of time trends in psychosocial disorders of youth across the second half of the twentieth century. It found evidence for substantial increases in rates of youth crime, alcohol and drug use, depression and suicide in most industrialized countries in the decades following the Second World War, slowing in some instances in the 1980s. Ten years on, we review findings on more recent trends in rates of these and other indicators of child and adolescent mental health. RECENT FINDINGS: Prevalence estimates for autism spectrum disorders have increased in recent decades, as has public and professional awareness of hyperactivity and attention deficits. Trends in adolescent conduct problems, and in alcohol and drug use, appear to reflect culture-specific influences. Rates of suicide among young males, and self-harm among females have risen in many countries in recent years; trends in emotional disorders are more varied, but there is little evidence

for any rise in rates of anorexia nervosa. Although some contributors to these trends have been identified, much remains to be learned about the key risks involved. SUMMARY: Monitoring time trends in child and adolescent mental health is essential for service planning; knowledge of changing trends can also provide important pointers to potential risk factors. Current data sources allow relatively reliable tracking of trends in some areas, but remain severely limited in others. Further research is needed to understand the mechanisms underlying recently identified trends in child and adolescent mental health.

Maughan B, Rowe R, Messer J, Goodman R, Meltzer H. Conduct disorder and oppositional defiant disorder in a national sample: developmental epidemiology. *J Child Psychol Psychiatry* 2004; 45(3):609-21. Abstract: BACKGROUND: Despite an expanding epidemiological evidence base, uncertainties remain over key aspects of the epidemiology of the 'antisocial' disorders in childhood and adolescence. METHODS: We used cross-sectional data on a nationally representative sample of 10,438 5-15-year-olds drawn from the 1999 British Child Mental Health Survey to examine age trends, gender ratios and patterns of comorbidity in DSM-IV Conduct Disorder (CD) and Oppositional Defiant Disorder (ODD). RESULTS: CD was significantly more common in boys than girls, and increased in prevalence with age. Among children who met diagnostic criteria for CD, status violations and other non-aggressive conduct problems increased with age, while aggressive symptoms became less common. Gender differences in ODD varied by reporter. Estimates of age trends in ODD depended heavily on treatment of overlaps with CD. Following DSM-IV guidelines (where ODD is not diagnosed in the presence of CD), rates of ODD fell with age; if that constraint was released, clinically significant rates of oppositionality persisted at similar levels from early childhood to middle adolescence. CD and ODD showed high levels of overlap, and both diagnoses showed substantial comorbidity with other non-antisocial disorders. CONCLUSIONS: Results from this large-scale study confirm and extend previous findings in the epidemiology of the disruptive behaviour disorders.

Max JE, Robin DA, Taylor HG *et al.* Attention function after childhood stroke. *J Int Neuropsychol Soc* 2004; 10(7):976-86. Abstract: We investigated attentional outcome after childhood stroke and orthopedic diagnosis in medical controls. Twenty-nine children with focal stroke lesions and individually matched children with clubfoot or scoliosis were studied with standardized attention and neuroimaging assessments. Stroke lesions were quite varied in location and commonly involved regions implicated in Posner's model of attention networks. Children with stroke lesions performed significantly more poorly regarding attention function

compared with controls. Performance on the Starry Night, a test demanding alerting and sensory-orienting but not executive attention function, was significantly associated with lesion size in the alerting and sensory-orienting networks but not the executive attention network. Furthermore, earlier age at lesion acquisition was significantly associated with poorer attention function even when lesion size was controlled. These findings support the theory of dissociable networks of attention and add to evidence from studies of children with diffuse and focal brain damage that early insults are associated with worse long-term outcomes in many domains of neuropsychological function. In addition, these results may provide clues towards the understanding of mechanisms underlying attention in children.

Maxeiner H. Demonstration and interpretation of bridging vein ruptures in cases of infantile subdural bleedings. *J Forensic Sci* 2001; 46(1):85-93. Abstract: Report of two cases of lethal infantile subdural bleedings (SDB). Bridging vein (BV) ruptures were directly proven as the source of the (minimal) SDB by a postmortem X-ray. In the controversial discussion concerning the causes of infantile SDB, proof of the occurrence of several BV ruptures is seen as an important sign of a trauma of significant degree. Although infantile SDB undoubtedly can result from accidental as well as intentional injuries, and therefore, the SDB itself does not allow far-reaching conclusions as to the cause of injury, the presence of several BV ruptures combined with an SDB of insignificant volume, in an infant dead or in a deep coma on clinical presentation, is not compatible with the supposition of a minor fall as the cause. We have not observed such findings as the result of a minor accidental event for more than 15 years.

Maxeiner H. [Evaluation of subdural hemorrhage in infants after alleged minor trauma]. *Unfallchirurg* 2001; 104(7):569-76. Abstract: QUESTIONING: Recently the discussion concerning the causes of infantile subdural bleedings (SDB) has become quite controversial. The widespread interpretation that most of these cases are the result of abuse, especially by the shaken-baby-syndrome, was doubted, and the role of (even minor) accidental events was emphasized. METHODS: This situation should be analyzed basing on the official statistics of the causes of death in the city of Berlin (1978-1998) and the autopsy material of our institute (1978-1999). RESULTS: In this period, approximately 440.000 children lived their first year of life in our city. Only 80 violent deaths of infants (up to 1 year old) were recorded in the official statistics, including 27 deaths due to blunt forces, with 24 lethal head injuries as the main group. Only two cases were attributed to "falls under unclear conditions"; all other accidental cases were the results of traffic accidents or falls from a height. No death due to an undoubted minor fall was

recorded, nor was any in our autopsy material. We investigated 10 cases of infantile SDB, all without skull fractures and gross brain injuries. Only 1 victim had a SDB of a significant volume; in all other cases only small amounts of blood were present in the subdural space. Bridging vein ruptures were directly demonstrated in 8 cases and were bilaterally in most instances; recently their detection has been simplified by postmortem x-ray using contrast material. All 10 cases were interpreted as typical acceleration-deceleration injuries (as in shaking), although only in 2 cases a confession of this procedure could be obtained. CONCLUSION: Comparing cases of accidental and non-accidental SDB in the literature, infantile SDB obviously cannot be looked at as a homogeneous entity: two quite different types should be kept separate: the patients suffering from an accidental SDB due to a minor fall mostly do not deteriorate immediately after the trauma, develop SDB of some volume, up to a space-occupying mass lesion, and have often a good prognosis. A lethal outcome is extremely uncommon; we have not observed a single case of an infantile lethal SDB resulting from such a minor injury for more than 20 years. The source of the SDB in those cases currently is unknown in most instances. The second group of infantile SDB includes the well-known group of shaken-baby-syndrome: no adequate history, infants dead or nearly dead on clinical presentation, often a poor outcome if the event is survived, typically no significant volume of SDB, and--according to our experiences--in all cases BV ruptures. This combination of several BV ruptures with no significant subdural bleeding is not compatible with a supposition of a minor fall causing this.

Maxeiner H. [A postmortem view on "pure" subdural hemorrhages in infants and toddlers]. *Klin Padiatr* 2002; 214(1):30-6. Abstract: In the last years, the discussion concerning the causes of infantile subdural hemorrhages became controversial. Many authors still suppose that child abuse is the predominant cause of such cases. On the other hand, reports presenting series of accidental cases were published, and the fear of an overdiagnosis of the shaken baby syndrome has been expressed. Our autopsy material concerning all lethal head injuries of infants and toddlers from 2 decades was reviewed. 17 of these 64 cases were characterized by the following: history of no trauma or only an insignificant event; children found dead or apnoic or in coma; no skull fractures; no focal brain injury; ruptures of several bridging veins but only minimal subdural bleeding. 11 victims were infants (1st year of life) and either 3 were 2 years resp. 3 - 6 years old; 50 % of all lethal head injuries of infants were of this type, while only 25 % resp. 10 % of the following age groups. None of these 17 cases was a result of a minor accident witnessed by unrelated persons. Abuse could be ascertained with a high degree of probability in most cases and remained quite likely in the others. Two different types of

subdural hemorrhages should be kept from another: a) patients suffering a moderate head injury from a minor accident which results in a subdural bleeding (from a small intracranial lesion) often do not deteriorate soon after the impact, develop a hemorrhage of significant volume, respond well to therapy and have a good prognosis. b) cases with a history of no or only of an insignificant trauma, infants dead or nearly dead on clinical presentation, often a poor outcome in cases of survival. There is typically no significant subdural bleeding despite multiple bridging vein ruptures in the majority of these cases: the subdural hemorrhage is here only a visible sign of a much more serious and general cerebral alteration, resulting in a rapid increase of intracranial pressure (often complicated by respiratory arrest) which prevents a significant bleeding into the subdural space. This combination of findings is typically found in victims of massive events (car occupants in high-velocity crashes) and not compatible with a supposition of a minor fall causing this.

May PA, Gossage JP. Estimating the prevalence of fetal alcohol syndrome. A summary. *Alcohol Res Health* 2001; 25(3):159-67.

Abstract: Since the late 1970s, many studies have reported on the prevalence of fetal alcohol syndrome (FAS), alcohol-related birth defects (ARBD), and alcohol-related neurodevelopmental disorders (ARND). The three main types of research methods used in these studies are passive surveillance, clinic-based studies, and active case ascertainment. This article describes each of these methods, including their strengths and weaknesses, and summarizes the estimated prevalence of FAS produced by each of these approaches. The maternal risk factors associated with FAS and other alcohol-related anomalies include advanced maternal age, low socioeconomic status, frequent binge drinking, family and friends with drinking problems, and poor social and psychological indicators. Overall, the available literature points to a prevalence rate of FAS of 0.5 to 2 cases per 1,000 births in the United States during the 1980s and 1990s.

Maybloom B, Champion Z. Development and implementation of a multi-centre information system for paediatric and infant critical care. *Intensive Crit Care Nurs* 2003; 19(6):326-41. Abstract: BACKGROUND: With no UK collective information system, a need existed to establish an integrated information system for public and private sector hospitals providing paediatric and infant critical care services. A lack of information in the past made it difficult for those procuring, providing and monitoring

services to make informed, evidence-based decisions using reliable integrated data. OBJECTIVES: To develop and implement a collective multi-purpose information system for paediatric and infant critical care that was easily adaptable to any UK infant or paediatric critical care setting. Information outputs had to fulfil policy requirements and meet the needs of stakeholders. METHOD: Two minimum datasets, corresponding data definitions, survey forms and a user database were developed through a process of consultation by utilising an information partnership. Design, content, development and implementation issues were identified, discussed and resolved through a co-ordinated collaborative process. RESULTS: Data collection was implemented in all London and Brighton National Health Service (NHS) general and cardio-thoracic paediatric intensive care (PIC) units, several private PIC units and one NHS tertiary referral neonatal unit (NNU) 24 months from project start. CONCLUSIONS: The development of universal integrated information systems for defined settings of care is achievable within reasonable timeframes; however, successful development and implementation requires working within an information partnership to maximise co-ordination, co-operation and collaboration. Those collecting and using data must be identified and involved in all aspects of development from project start. Financial and manpower resources must be well planned. Datasets should be as small as possible in order to make the collection of complete and valid data realistically achievable. When considering service-based information needs, considerable thought should be given to a multi-purpose; multi-use approach based on the most refined minimum dataset possible.

Mayer KL, Ho HS, Goodnight JE Jr. Childbearing and child care in surgery. *Arch Surg* 2001; 136(6):649-55. Abstract: HYPOTHESIS: The responsibility for childbearing and child care has a major effect on general surgical residency and subsequent surgical practice. METHODS: A survey of all graduates from a university general surgical training program between 1989 and 2000. RESULTS: Twenty-seven women and 44 men completed general surgical training at our university during the period, and 42 (59%) responded to our survey. The age at completion of the residency was 34.0 +/- 2.2 years for men and 33.9 +/- 2.8 years for women. During residency, 64% (14/22) of the men and 15% (3/20) of the women had children. At the time of the survey, 21 (95%) of the men and 8 (40%) of the women had children. Most residents (24 [57%] of 42) relied on their spouse for child care. During surgical practice, 18 (43%) indicated that they rely on their spouse; 19 (45%) use day care, home care, or both; and (8%) of 26 are unsatisfied with their current child care arrangement. During training, 38% (5/13) of men and 67% (2/3) of women took time off for maternity leave, paternity leave, or child care. Two of 3 surgeons would like to have had more time off during residency; most

men (70%, or 7 of 10) recommended a leave of 1 to 3 months, and all women preferred a 3-month maternity or child care leave of absence. During surgical practice, only 12% (2/17) of men but 64% (7/11) of women have taken time off for either childbearing or child care. Half of the respondents (21/42) have a formal leave of absence policy at work, 52% (11/21) of which are paid leave programs. Although the workweek of our practicing graduates is 69 +/- 16 hours for men and 64 +/- 12 hours for women, 62% (26/42) spend more than 20 hours per week parenting. More than 80% (27/32) would consider a part-time surgical practice for more parenting involvement; one third of the responders suggested that 30 hours a week constitutes a reasonable part-time practice, one third preferred fewer than 30 hours, and one third favored more than 30 hours per week. Data are presented as mean +/- SD. CONCLUSIONS: Childbearing and child care may have an enormous impact on one's decision to pursue a career in surgery. To attract and retain the best candidates for future surgeons, formal policies on the availability of child care services in the residency program and the workplace should be studied and implemented. Furthermore, national studies are needed to define appropriate, acceptable workweeks for part-time or flexible practices and the duration of leaves of absence for childbearing or child care.

Mayor S. WHO report shows public health impact of violence. *BMJ* 2002; 325(7367):731.

Maziak W. Smoking in Syria: profile of a developing Arab country. *Int J Tuberc Lung Dis* 2002; 6(3):183-91. Abstract: One of the main obstacles to tobacco control in the Middle East lies in the shortage of reliable, standardised data on the spread and patterns of tobacco use in society. In Syria, a project aiming at drawing an epidemiological map of the tobacco epidemic in this country was started 4 years ago. Overall, nine studies have resulted, with a total of 6780 participants. The crude prevalence of current smoking among adults in Syria, based on combined information from all studies, is 48% and 9% for males and females, respectively. The prevalence of current smoking among high school adolescents is 16% and 7% for boys and girls, respectively, and was strongly associated with parental and sibling smoking. High school students from families with parents and/or siblings who smoked were 4.4 times more likely to be current smokers than those from non-smoking families. The biggest influx of new smokers among males in Syria is occurring in the early twenties, but an earlier pattern can occur among youths with low academic performance or socioeconomic status. Smoking in women, evaluated by data from physicians, tends to start later than in men and continues to increase with age. Women's smoking in

Syria is related to their level of social liberalisation. Data show that active smoking is associated with an increased risk of respiratory diseases among smokers, and that exposure to environmental tobacco smoke (ETS) is associated with an increased risk of respiratory symptoms in children. Knowledge about the harmful effects of smoking and the desire to quit are disproportionate to the rate of successful cessation. The evidence collected indicates possible avenues for tobacco control in Syria, including price increases, smoking cessation programmes, restriction of adolescents' access to cigarettes, and intensive prevention work among women.

Mbassa Menick D, Ngoh F. [Psychological mistreatment of children with sickle cell disease in Cameroon: description and analysis of 1 case]. *Med Trop (Mars)* 2001; 61(2):163-8.  
Abstract: Psychological maltreatment of a children with sickle-cell disease is a form of parental dysfunction provoked by a crisis situation. In most cases, this type of child abuse involves a relatively harmonious family going through a period of adaptation that jeopardizes its internal equilibrium. The weakest components of the family, i.e., the children, become the scapegoats for the crisis. After a brief description of this disorder, the authors analyze the different causes that lead to eruption of intra-familial violence. Several cultural, social, and economic factors combine to trigger the maltreatment to which hapless children with sickle-cell disease fall victim. Special legislation to provide appropriate child care is the only alternative to prevent these situations from becoming chronic subject only to the socio-economic conditions of the parents and prevailing ethos.

McAlonan GM, Cheung V, Cheung C *et al.* Mapping the brain in autism. A voxel-based MRI study of volumetric differences and intercorrelations in autism. *Brain* 2005; 128(Pt 2):268-76.  
Abstract: Autism is a disorder of neurodevelopment resulting in pervasive abnormalities in social interaction and communication, repetitive behaviours and restricted interests. There is evidence for functional abnormalities and metabolic dysconnectivity in 'social brain' circuitry in this condition, but its structural basis has proved difficult to establish reliably. Explanations for this include replication difficulties inherent in

'region of interest' approaches usually adopted, and variable inclusion criteria for subjects across the autism spectrum. Moreover, despite a consensus that autism probably affects widely distributed brain regions, the issue of anatomical connectivity has received little attention. Therefore, we planned a fully automated voxel-based whole brain volumetric analysis in children with autism and normal IQ. We predicted that brain structural changes would be similar to those previously shown in adults with autism spectrum disorder and that a correlation analysis would suggest structural dysconnectivity. We included 17 stringently diagnosed children with autism and 17 age-matched controls. All children had IQ >80. Using Brain Activation and Morphological Mapping (BAMM) software, we measured global brain and tissue class volumes and mapped regional grey and white matter differences across the whole brain. With the expectation that volumes of interconnected regions correlate positively, we carried out a preliminary exploration of 'connectivity' in autism by comparing the nature of inter-regional grey matter volume correlations with control. Children with autism had a significant reduction in total grey matter volume and significant increase in CSF volume. They had significant localized grey matter reductions within fronto-striatal and parietal networks similar to findings in our previous study, and additional decreases in ventral and superior temporal grey matter. White matter was reduced in the cerebellum, left internal capsule and fornices. Correlation analysis revealed significantly more numerous and more positive grey matter volumetric correlations in controls compared with children with autism. Thus, using similar diagnostic criteria and image analysis methods in otherwise healthy populations with an autistic spectrum disorder from different countries, cultures and age groups, we report a number of consistent findings. Taken together, our data suggest abnormalities in the anatomy and connectivity of limbic-striatal 'social' brain systems which may contribute to the brain metabolic differences and behavioural phenotype in autism.

McBeth J, Morris S, Benjamin S, Silman AJ, Macfarlane GJ. Associations between adverse events in childhood and chronic widespread pain in adulthood: are they explained by differential recall? *J Rheumatol* 2001; 28(10):2305-9.  
Abstract: OBJECTIVE: Clinic based studies suggest that adverse events in childhood may predispose to chronic pain in adult life. These have been conducted on highly selected groups, and it is unknown whether these relationships hold in the general population and to what extent the increased rate of adverse childhood events in persons with pain is an artefact of differential reporting. We examined the hypothesis that chronic widespread pain was associated with reports of adverse experiences in childhood and whether any observed relationships could be explained by differential recall.

**METHODS:** A cross sectional population based screening survey was conducted. Subjects completed a questionnaire that included assessments of pain and psychological state. In total, 296 subjects who had demonstrated psychological distress were randomly selected and had a detailed interview, which included an assessment of 14 adverse childhood experiences. Medical records relating to childhood were also examined for those subjects. **RESULTS:** The prevalence of self-reported adverse childhood experiences was greatest in adult subjects with current chronic widespread pain. Exposure to illness in family members, parental loss, operations, and abuse were all associated with increased, but nonsignificant, odds of having chronic widespread pain versus those without such exposures. However the only statistically significant association was with childhood hospitalizations. From medical record information the associations of hospitalizations (OR 5.1, 95% CI 2.0-13.0) and operations (OR 3.0, 95% CI 1.2-7.2) with pain previously noted were partly explained by differential recall between subjects with and without pain: hospitalizations, OR 2.2, 95% CI 0.9-5.5; operations, OR 1.2, 95% CI 0.5-3.4. **CONCLUSION:** Although several reported adverse events in childhood were observed to be associated with chronic widespread pain in adulthood, only reports of hospitalizations were significantly associated. Validation of self-reported exposures suggests that there was differential recall of past events among those with and without pain, and this differential recall explained the association between hospitalizations and current chronic pain. Such differential recall may explain other observations of an association between reports of adverse childhood events and chronic pain in adulthood.

McBurney PG, Simpson KN, Darden PM. Potential cost savings of decreased emergency department visits through increased continuity in a pediatric medical home. *Ambul Pediatr* 2004; 4(3):204-8. Abstract: **PURPOSE:** To determine the potential cost savings of decreased emergency department (ED) visits resulting from increased continuity of care provided in a pediatric medical home. **METHODS:** An economic modeling study comparing the cost of ED visits associated with average continuity of care versus the cost of ED visits associated with a 10% point increase in continuity was performed. This model's premise is that increased continuity will decrease care in the ED. Parameters of the model included average continuity of care and expected use of the ED by pediatric patients as well as the relationship between these two variables. Parameters were estimated from the literature. Average continuity, as measured by the Continuity of Care Index by Bice and Boxerman, was determined to be 40%. Average ED use was estimated to be 0.68 visits/child per year. Continuity of care was stratified into low, medium, and high levels. The Medical University of South Carolina's ED charges were used. An average pediatric practice was estimated to contain 2000 patients. **RESULTS:** Two hypothetical practices of 2000 patients each were created to represent pediatric medical homes: practice 1 received 40% continuity and practice 2 received 50%. The model's outcome was measured in terms of expected ED charges per practice averted over a 1-year period. Increasing continuity of care by 10% points yielded a decline in expected ED visits from 1362 to 1290 per practice: 19,905 US dollars was saved. **CONCLUSION:** Continuity of care can yield many benefits, including cost savings from decreased charges associated with less frequent ED use.

McBurnett K, Kerckhoff C, Capasso L *et al.* Antisocial personality, substance abuse, and exposure to parental violence in males referred for domestic violence. *Violence Vict* 2001; 16(5):491-506. Abstract: This study investigated whether childhood disruptive behavior (hyperactivity, oppositional-defiance, conduct problems) plus adult psychopathic adjustment are associated with domestic violence. Adult males (n = 66) in diversion programs completed the Wender Utah Rating Scale (WURS), MMPI Psychopathic Deviate scale (PD), Conflict Tactics Scales representing themselves and their parents, and substance use measures. Substance use and lifespan antisocial personality (measured by high WURS and PD scores) were robust predictors of verbal and moderate physical domestic abuse. Violence in the family of origin was associated with abuse when tested alone, but failed to exhibit unique association with abuse when other predictors were taken into account. The possibility that antisocial batterers respond to contingencies by moderating physical harm, while persisting at psychological harm, is discussed.

McCabe KM, Hough R, Wood PA, Yeh M. Childhood and adolescent onset conduct disorder: a test of the developmental taxonomy. *J Abnorm Child Psychol* 2001; 29(4):305-16. Abstract: Hypotheses generated by a developmental taxonomy that distinguishes between childhood and adolescent onset conduct disorders were tested. Hypotheses predicted that (1) individual and familial factors would be more strongly related to childhood onset conduct disorder, whereas ethnic minority status and exposure to deviant peers would be more strongly related to adolescent onset conduct disorder and (2) individuals with childhood onset disorder would be more likely to commit violent and victim oriented offenses than individuals with adolescent onset conduct disorder. The first hypothesis was strongly supported and the second hypothesis was partially supported. Implications for early identification of youth at risk for chronic offending are discussed.

McCabe KM, Lansing AE, Garland A, Hough R. Gender differences in psychopathology, functional impairment, and familial risk factors among adjudicated

delinquents. *J Am Acad Child Adolesc Psychiatry* 2002; 41(7):860-7.

Abstract: OBJECTIVE: To test the hypotheses that female juvenile delinquents would have higher rates of psychological symptoms, DSM-IV psychiatric and substance use disorders, functional impairment, and familial risk factors than male juvenile delinquents. METHOD: A stratified random sample of adjudicated delinquents (n = 513 males, n = 112 females) was drawn from San Diego County administrative databases. Of those sampled youths who could be located, 65.7% completed interviews. Psychological symptoms, DSM-IV diagnoses, and familial risk factors were assessed between October 1997 and January 1999. RESULTS: Female delinquents scored higher on parent and self-report measures of psychological symptoms and had higher rates of DSM-IV mental disorders than did male delinquents. Girls also experienced greater incidences of physical, emotional, and sexual abuse; physical neglect; and family history of mental illness than their male counterparts. No gender differences were found on parental ratings of youth functional impairment, substance use disorders, comorbidity, or parental history of antisocial behavior. CONCLUSIONS: Findings indicated that female adjudicated delinquents have significantly higher rates of psychopathology, maltreatment history, and familial risk factors than males and suggest that the mental health needs of girls in juvenile justice deserve increased attention.

McCarter-Spaulding DE, Kearney MH. Parenting self-efficacy and perception of insufficient breast milk. *J Obstet Gynecol Neonatal Nurs* 2001; 30(5):515-22. Abstract: OBJECTIVE: Insufficient breast milk is a major reason why mothers give up breastfeeding and may be related to low levels of maternal confidence. This study explored the relationship between parenting self-efficacy (PES) and perception of insufficient breast milk. DESIGN: Cross-sectional descriptive correlational study. SETTING: Four private primary care pediatric practices in the northern United States. PARTICIPANTS: Sixty breastfeeding mothers of infants ages 1 to 11 weeks. PROCEDURES: Mothers were recruited during well-baby pediatric visits. They returned completed questionnaires by mail. Data were analyzed using descriptive statistics, t tests, and multiple regression analysis. MAIN OUTCOME MEASURE: The Perception of Insufficient Milk (PIM) questionnaire, an investigator-developed instrument. RESULTS: There was a significant correlation ( $r = .487$ ,  $p < .01$ ) between the self-efficacy and perceived insufficient milk scores. Regression analysis revealed that 23% of the variance in PIM was explained by PES, after maternal age, education, and parity had been taken into account. CONCLUSIONS: Although further research is needed to refine the measurement of perceived insufficient milk and differentiate breastfeeding self-efficacy from general parenting self-efficacy, nursing interventions to enhance self-efficacy

may improve mothers' confidence in the adequacy of their milk supply.

McClelland GM, Elkington KS, Teplin LA, Abram KM. Multiple substance use disorders in juvenile detainees. *J Am Acad Child Adolesc Psychiatry* 2004; 43(10):1215-24.

Abstract: OBJECTIVE: To estimate the 6-month prevalence of multiple substance use disorders (SUDs) among juvenile detainees by demographic subgroups (sex, race/ethnicity, age). METHOD: Participants were a randomly selected sample of 1,829 African American, non-Hispanic white, and Hispanic detainees (1,172 males, 657 females, aged 10 to 18). Patterns and prevalence of DSM-III-R multiple SUDs were assessed using the Diagnostic Interview Schedule for Children Version 2.3. The authors used two-tailed F and t tests with an alpha of .05 to examine combinations of SUDs by sex, race/ethnicity, and age. RESULTS: Nearly half of the detainees had one or more SUDs; more than 21% had two or more SUDs. The most prevalent combination of SUDs was alcohol and marijuana use disorders (17.25% females, 19.42% males). Among detainees with any SUD, almost half had multiple SUDs. Among detainees with alcohol use disorder, more than 80% also had one or more drug use disorders. Among detainees with a drug use disorder, approximately 50% also had an alcohol use disorder. CONCLUSIONS: Among detained youths with any SUD, multiple SUDs are the rule, not the exception. Substance abuse treatments need to target detainees with multiple SUDs who, upon release, return to communities where services are often unavailable. Clinicians can help ensure continuity of care by working with juvenile courts and detention centers.

McCloskey KA, Raphael DN. Adult perpetrator gender asymmetries in child sexual assault victim selection: results from the 2000 National Incident-Based Reporting System. *J Child Sex Abus* 2005; 14(4):1-24. Abstract: Data from the 2000 National Incident-Based Reporting System (NIBRS) show that while males make up about nine out of every 10 adult sexual assault perpetrators, totaling about 26,878 incidents within the reporting period, females account for about one out of 10 perpetrators, totaling about 1,162 incidents. Male sexual assault perpetrators offend against child victims about 25% of the time and predominantly choose female child victims, whereas female perpetrators offend against child victims about 40% of the time and choose child victims of both genders equally. Male perpetrators offend against adolescent victims about 40% of the time, and once again tend to choose female adolescent victims. Female perpetrators offend against adolescent victims a comparable amount of time (about 45%), and for forcible offenses (rape, sodomy, sexual assault with an object, and forcible fondling) choose adolescent victims of both genders equally, while for non-forcible offenses (non-forcible incest and statutory rape) they tend to choose predominantly male victims.

- Finally, adult male sexual assault perpetrators choose adult victims about 36% of the time while female perpetrators choose adult victims only 16% of the time. Implications for professionals are discussed, including recommendations to aid in correct identification of adult perpetrators and child/adolescent victims of sexual assault.
- McCloskey LA, Stuewig J. The quality of peer relationships among children exposed to family violence. *Dev Psychopathol* 2001; 13(1):83-96. Abstract: Three hundred sixty-three school-aged children from maritally violent and nonviolent families were interviewed about their friendship networks, frequency of social contact, the interpersonal quality of their friendships, and hostile attributional biases. Mothers answered items from the Child Behavior Checklist about peer conflict. Children did not differ on the number of friends they claimed or their frequency of contact with peers. However, children exposed to marital violence reported feeling more lonely and having more conflict with a close friend. Their mothers also reported them as having more problems with peers. In addition, children with punitive mothers had more conflict with a best friend. Residing in a shelter added further to children's feelings of loneliness, with one third having no best friend. Children's attributional biases were unrelated to the quality of their peer relations or any other index of peer functioning. Results are discussed in terms of an attachment framework. Findings confirm that it is important to examine the quality of relationships to determine how children at risk fare in their social lives.
- McCoy ML. Factors impacting the assessment of maternal culpability in cases of alleged fetal abuse. *J Drug Educ* 2003; 33(3):275-88. Abstract: These studies explored attitudes toward maternal culpability in cases of alleged fetal abuse. In experiment one, general culpability for the use of various substances during pregnancy was assessed as well as the impact of other potentially relevant factors. One hundred and twenty students completed the survey. Participants overwhelmingly supported treating drug use by pregnant women as a criminal offense. With regard to the assessment of more specific questions, the lack of consensus regarding what factors effect culpability is striking. Experiment two examined the possible impact of the mothers' race (White or Black) and social class (Poor or Middle class) on the assessment of culpability. One hundred and sixty-four community members responded to a survey sent to randomly selected persons in upstate South Carolina. The results indicate that at least in response to a brief, written, case scenario, neither race nor social class make a large impact on participants' sanction recommendations.

- McDermott BM, Jaffa T. Eating disorders in children and adolescents: an update. *Curr Opin Psychiatry* 2005; 18(4):407-10. Abstract: PURPOSE OF REVIEW: Children and adolescents with eating disorders frequently present to child mental health and paediatric services and have significant morbidity, psychosocial impairment and mortality. Efforts to treat these individuals have been hampered by a poor evidence base for effective interventions. This article reviews research published during 2004 with a primary focus on this challenging clinical area. RECENT FINDINGS: Research published during 2004 has replicated past epidemiological findings and expanded our understanding of the relationship of family meal structure and disordered eating. Research has provided assistance in the well known clinical conundrums of excessive exercising in anorexia nervosa and predicting when return of menses will occur. There has also been clarification of adolescent bingeing. Potential advances include a new, noninvasive method of measuring body composition and investigations in adolescents on leptin, neuro and gastrointestinal peptides. Importantly, further evidence of the effectiveness of family therapy for anorexia nervosa and short-term benefits from intervention programs have been published. SUMMARY: The research base that will influence clinical practice in child and adolescent eating disorders is increasing. More research is required in all areas of intervention.
- McDonald EM, Solomon B, Shields W *et al.* Evaluation of kiosk-based tailoring to promote household safety behaviors in an urban pediatric primary care practice. *Patient Educ Couns* 2005; 58(2):168-81. Abstract: We tested a kiosk-based tailoring intervention with a sample of 144 parents of young children using a two-group randomized controlled design to evaluate the kiosk. Intervention group parents (n = 70) answered 50 questions at a practice-based kiosk and they and their child's physician received immediate feedback reports of their injury prevention needs. Four weeks later, both control (n = 74) and intervention parents completed a telephone interview. Safety knowledge, beliefs, and practices were compared at follow-up. Compared to control group parents, intervention group parents were more knowledgeable about the inappropriateness of young children riding in the front seat of a car (16% versus 5%, p < 0.05), less likely to believe that teaching a child to mind you is the best way to prevent injuries (64% versus 86%, p < 0.05), and more likely to report that they "have syrup of ipecac" (34% versus 9%, p <

0.001) and "know how to use" it (24% versus 4%,  $p < 0.002$ ). This study provides further support for the use of tailored communication to address the prevention of injuries to young children but calls for continued investigation in the area.

McDougle CJ, Stigler KA, Posey DJ. Treatment of aggression in children and adolescents with autism and conduct disorder. *J Clin Psychiatry* 2003; 64 Suppl 4:16-25.

Abstract: The optimal clinical management of aggression in children and adolescents involves both behavioral and pharmacologic intervention strategies. This article reviews medication treatments for youngsters with autistic disorder and conduct disorder, conditions for which the pharmacologic management of aggression is often necessary. Efficacy results and associated adverse effects from selected clinical trials of most classes of psychotropic medications are discussed. While preliminary progress has been made in the development of medication treatments for these serious disorders of youth, additional controlled research and longitudinal studies are needed to better understand the efficacy and tolerability of currently available compounds within each diagnostic group.

McDowell BM. Volunteering--a community partnership. *J Spec Pediatr Nurs* 2002; 7(3):121-2.

McElroy PD, Rothenberg RB, Varghese R *et al.* A network-informed approach to investigating a tuberculosis outbreak: implications for enhancing contact investigations. *Int J Tuberc Lung Dis* 2003; 7(12 Suppl 3):S486-93.

Abstract: BACKGROUND: To elucidate networks of Mycobacterium tuberculosis transmission, it may be appropriate to characterize the types of relationships among tuberculosis (TB) cases and their contacts (with and without latent TB infection) in addition to relying on traditional efforts to distinguish 'close' from 'casual' contacts. SETTING: A TB outbreak in a US low incidence state. OBJECTIVE: To evaluate whether social network analysis can provide insights into transmission settings that might otherwise go unrecognized by routine practices. DESIGN: All adult outbreak-associated cases ( $n = 19$ ) and a convenience sample of their contacts with and without latent TB infection (LTBI) ( $n = 26$ ) were re-interviewed in 2001 using a structured questionnaire. Network analysis software was used to create diagrams illustrating important persons within the outbreak network, as well as types of activities TB cases engaged in with their contacts. RESULTS: Drug use and drug sharing were more commonly reported among cases and their infected contacts than among contacts without LTBI. TB cases central to the outbreak network used crack cocaine, uncovering the need to focus control efforts on specific sites and persons involved in illicit drug use. CONCLUSION: Outbreaks occur even in areas with

low TB incidence, frequently among groups whose drug use or other illegal activities complicate control efforts. TB programs should consider the use of network analysis as a supplement to routine contact investigations to identify unrecognized patterns of M. tuberculosis transmission.

McEvoy M, Lee C, O'Neill A *et al.* Are there universal parenting concepts among culturally diverse families in an inner-city pediatric clinic? *J Pediatr Health Care* 2005; 19(3):142-50.

Abstract: INTRODUCTION: Cultural competence is necessary in providing care to culturally diverse families. Numerous studies have emphasized similarities and differences between predetermined cultural groups, yet few have studied groups across cultures. This project aimed to investigate parenting concepts, which in this context pertains to philosophy of parenting and child care practices across cultures. METHOD: Using a grounded theory approach, ethnographic interviews of 46 families representing 27 countries were taped, transcribed, and analyzed. RESULTS: Similarities in parenting concepts were found among families. Teaching values and respect and the need for strict discipline were important. A sense of community, family, and spirituality/religion was strong. Television was viewed as educational and parents anticipated opportunities for jobs and higher education for their children. Parents were more inclined to use medical treatments than home remedies for acute illnesses, which may have been linked to the finding that their providers had a strong influence. Parents feared children playing alone outdoors; distrusted nonfamily babysitters; and felt conflicted between a desire for cultural preservation versus assimilation. DISCUSSION: Universal concepts in parenting philosophies and practices exist among culturally diverse families. Providers may approach anticipatory guidance by addressing global parental concerns that transcend culture in order to relieve time constraints and the overwhelming task of being knowledgeable about all cultures.

McFarlane A, Clark CR, Bryant RA *et al.* The impact of early life stress on psychophysiological, personality and behavioral measures in 740 non-clinical subjects. *J Integr Neurosci* 2005; 4(1):27-40.

Abstract: Early Life Stress (ELS) has been associated with a range of adverse outcomes in adults, including abnormalities in electrical brain activity [1], personality dimensions [40], increased vulnerability to substance abuse and depression [14]. The present study seeks to quantify these proposed effects in a large sample of non-clinical subjects. Data for the study was obtained from The Brain Resource International Database (six laboratories: two in USA, two in Europe, two in Australia). This study analyzed scalp electrophysiological data (EEG eyes open, closed and target auditory oddball data) and personality (NEO-FFI), history of addictive substance use and ELS) data

that was acquired from 740 healthy volunteers. The ELS measures were collected via a self-report measure and covered a broad range of events from childhood sexual and physical abuse, to first-hand experience of traumatizing accidents and sustained domestic conflict [41]. Analysis of covariance, controlling for age and gender, compared EEG data from subjects exposed to ELS with those who were unexposed. ELS was associated with significantly decreased power across the EEG spectrum. The between group differences were strongest in the eyes closed paradigm, where subjects who experienced ELS showed significantly reduced beta ( $F_{1,405}=12.37$ ,  $p=.000$ ), theta ( $F_{1,405}=20.48$ ,  $p=.000$ ), alpha ( $F_{1,405}=9.65$ ,  $p=.002$ ) and delta power ( $F_{1,450}=36.22$ ,  $p=.000$ ). ELS exposed subjects also showed a significantly higher alpha peak frequency ( $F_{1,405}=6.39$ ,  $p=.012$ ) in the eyes closed paradigm. Analysis of covariance on ERP components revealed that subjects who experienced ELS had significantly decreased N2 amplitude ( $F_{1,405}=7.73$ ,  $p=.006$ ). Analyses of variance conducted on measures of personality revealed that subjects who experienced ELS had significantly higher levels of neuroticism ( $F_{1,264}=13.39$ ,  $p=.000$ ) and openness ( $F_{1,264}=17.11$ ,  $p=.000$ ), but lower levels of conscientiousness, than controls ( $F_{1,264}=4.08$ ,  $p=.044$ ). The number of ELS events experienced was shown to be a significant predictor of scores on the DASS questionnaire [27], which rates subjects on symptoms of depression ( $F_{3,688}=16.44$ ,  $p=.000$ ,  $R^2=.07$ ), anxiety ( $F_{3,688}=14.32$ ,  $p=.000$ ,  $R^2=.06$ ) and stress ( $F_{3,688}=20.02$ ,  $p=.000$ ,  $R^2=.08$ ). Each additional early life stressor was associated with an increase in these scores independent of age, gender and the type of stressor. Furthermore, the number of ELS experiences among smokers was also found to be a positive predictor of the nicotine dependency score (Faegstrom Test For Nicotine Dependence, [19]) ( $F_{3,104}=10.99$ ,  $p=.000$ ,  $R^2=.24$ ), independent of age, gender and type of stressor. In conclusion, we highlight the impact of a history of ELS showed significant effects on brain function (EEG and ERP activity), personality dimensions and nicotine dependence.

McGarvey TP, Haen C. Intervention strategies for treating traumatized siblings on a pediatric inpatient unit. *Am J Orthopsychiatry* 2005; 75(3):395-408. Abstract: This article examines the course of treatment for 2 traumatized siblings in an acute inpatient child psychiatric unit following severe physical abuse by their mother. In treating these 2 boys, the authors used intervention strategies that can be applied to the treatment of other traumatized siblings in institutional settings. Issues of self-worth, survivor guilt, and conflictual sibling dynamics are illustrated as they relate to the treatment. In addition, transference-countertransference dynamics are examined.

McGee R, Williams S, Nada-Raja S. Is cigarette smoking associated with suicidal ideation among young people? *Am J Psychiatry* 2005; 162(3):619-20. Abstract: OBJECTIVE: The authors examined the association between suicidal ideation in early adulthood and daily tobacco smoking in a community sample of adolescents. METHOD: Participants were enrolled in a longitudinal study of health and development. The factors of disadvantage, impulsiveness, stress, depressed mood, tobacco smoking, other substance use, and parental attachment were included in multivariate modelling of suicidal ideation. RESULTS: Data on tobacco use were available for 764 participants. Early tobacco smoking was significantly predictive of later suicidal ideation, but there was no longer a significant relationship when high levels of stress and depression and low levels of parental attachment in adolescence were included in the multivariate model. CONCLUSIONS: Tobacco smoking in adolescence does not appear to elevate the risk of later suicidal ideation.

McGillicuddy NB, Rychtarik RG, Morsheimer ET. Psychometric evaluation of the parent situation inventory: a role-play measure of coping in parents of substance-using adolescents. *Psychol Assess* 2004; 16(4):386-90.

Abstract: This article reports on the generalizability, reliability, and construct validity of the Parent Situation Inventory (PSI), a role-play measure of coping skills in parents experiencing problems from an adolescent's drug and alcohol use. Generalizability was robust (.80) and alternate form and test-retest reliability were satisfactory. PSI skillfulness was negatively related to the parent's own substance use and to the adolescent's alcohol use. The PSI shows promise as a reliable and potentially valid measure of coping in this population and has direct implications for developing and evaluating skill-based parent training programs.

McGinn D. Father fixit. *Newsweek* 2002; 139(19):42-3.

McGlade MS, Saha S, Dahlstrom ME. The Latina paradox: an opportunity for restructuring prenatal care delivery. *Am J Public Health* 2004; 94(12):2062-5. Abstract: Latina mothers in the United States enjoy surprisingly favorable birth outcomes despite their social disadvantages. This "Latina paradox" is particularly evident among Mexican-born women. The social and cultural factors that contribute to this paradox are maintained by community networks--informal systems of prenatal care that are composed of family, friends, community members, and lay health workers. This informal system confers protective factors that provide a behavioral context for healthy births. US-born Latinas are losing this protection, although it could be maintained with the support of

community-based informal care systems. We recommend steps to harness the benefits of informal systems of prenatal care in Latino communities to meet the increasing needs of pregnant Latina women.

McGoodwin L, McKeown T. Poisoning trends and the importance of educating patients about poison prevention. *J Okla State Med Assoc* 2004; 97(3):127-30.

Abstract: Medical professionals are recognized as a vital link in communities for education and treatment of poisoning exposures. The Oklahoma Poison Control Center (OPCC) is a resource for medical professionals as well as the public. Nationally and in Oklahoma, among all age groups, analgesics are responsible for the most fatalities. Trends in common exposures in the age 5 and younger age group and the 13 through 19 age group, an acetaminophen protocol, information about the poison center and HIPPA privacy regulations, poison prevention tips and where to obtain educational materials are outlined. National Poison Prevention Week, March 21-27, 2004, is an excellent time to educate all age groups about poison prevention techniques and what to do when there is a poisoning emergency. Board certified toxicologists, pharmacists and registered nurses are available 24 hours a day, 7 days a week by calling 1-800-222-1222.

McGough JJ, Smalley SL, McCracken JT *et al*. Psychiatric comorbidity in adult attention deficit hyperactivity disorder: findings from multiplex families. *Am J Psychiatry* 2005; 162(9):1621-7.

Abstract: OBJECTIVE: Patterns of psychiatric comorbidity were assessed in adults with and without attention deficit hyperactivity disorder (ADHD) identified through a genetic study of families containing multiple children with ADHD. METHOD: Lifetime ADHD and comorbid psychopathology were assessed in 435 parents of children with ADHD. Rates and mean ages at onset of comorbid psychopathology were compared in parents with lifetime ADHD, parents with persistent ADHD, and those without ADHD. Age-adjusted rates of comorbidity were compared with Kaplan-Meier survival curves. Logistic regression was used to assess additional risk factors for conditions more frequent in ADHD subjects. RESULTS: The parents with ADHD were significantly more likely to be unskilled workers and less likely to have a college degree. ADHD subjects had more lifetime psychopathology; 87% had at least one and 56% had at least two other psychiatric disorders, compared with 64% and 27%, respectively, in non-ADHD subjects. ADHD was associated with greater disruptive behavior, substance use, and mood and anxiety disorders and with earlier onset of major depression, dysthymia, oppositional defiant disorder, and conduct disorder. Group differences based on Kaplan-Meier age-corrected risks were consistent with those for raw frequency distributions. Male sex added risk for disruptive behavior disorders. Female sex and

oppositional defiant disorder contributed to risk for depression and anxiety. ADHD was not a significant risk factor for substance use disorders when male sex, disruptive behavior disorders, and socioeconomic status were controlled. CONCLUSIONS: Adult ADHD is associated with significant lifetime psychiatric comorbidity that is not explained by clinical referral bias.

McGreevy D. Risks and benefits of the single versus the triple MMR vaccine: how can health professionals reassure parents? *J R Soc Health* 2005; 125(2):84-6. Abstract: Measles, mumps and rubella (MMR) are all preventable but infectious diseases caused by viruses. A particular study by Wakefield *et al* suggests that there are potentially adverse effects of having the triple MMR vaccine. This has been reported widely by the media and has caused alarm to parents of young children, probably contributing to the decline in its uptake. In order to provide the context for the debate regarding the single versus the triple vaccine, this paper briefly appraises firstly, the Wakefield *et al* research paper that has led to public health concerns and secondly, a more rigorous research study (Madsen *et al*) that contradicts the findings; the paper then explores the risks and benefits of the single and the triple MMR vaccine programmes, finally providing a short discussion on factors that might influence the decision-making process by parents when faced with the dilemma of not having their child vaccinated, or opting for either the single or triple vaccination programme.

McHaffie HE, Fowlie PW, Hume R, Laing IA, Lloyd DJ, Lyon AJ. Consent to autopsy for neonates. *Arch Dis Child Fetal Neonatal Ed* 2001; 85(1):F4-7. Abstract: OBJECTIVES: To determine parents' views on autopsy after treatment withdrawal. DESIGN: Face to face interviews with 59 sets of bereaved parents (108 individual parents) for whose 62 babies there had been discussion of treatment withdrawal. RESULTS: All except one couple were asked for permission for postmortem examination; 38% refused. The main reasons for declining were concerns about disfigurement, a wish to have the child left in peace, and a feeling that an autopsy was unnecessary because the parents had no unanswered questions. The diagnosis, the age of the child, and the approach of the consultant appeared to influence consent rates. Of those who agreed to autopsies, 92% were given the results by the neonatologist concerned. Whether or not they had agreed to the procedure, at 13 months no parent expressed regrets about their decision. CONCLUSIONS: Autopsy rates in the East of Scotland stand at 62%. Parents' perceptions are an important element in consent to postmortem examination.

McHaffie HE, Laing IA, Parker M, McMillan J. Deciding for imperilled newborns: medical authority or parental

autonomy? *J Med Ethics* 2001; 27(2):104-9.  
Notes: GENERAL NOTE: KIE: McHaffie, Hazel E; Laing, Ian A; Parker, Michael; McMillan, John  
GENERAL NOTE: KIE: 13 refs.  
GENERAL NOTE: KIE: KIE Bib: allowing to die/infants

Abstract: The ethical issues around decision making on behalf of infants have been illuminated by two empirical research studies carried out in Scotland. In-depth interviews with 176 medical and nursing staff and with 108 parents of babies for whom there was discussion of treatment withholding/withdrawal, generated a wealth of data on both the decision making process and the management of cases. Both staff and parents believe that parents should be involved in treatment limitation decisions on behalf of their babies. However, whilst many doctors and nurses consider the ultimate responsibility too great for families to carry, the majority of parents wish to be the final arbiters. We offer explanations for the differences in perception found in the two groups. The results of these empirical studies provide both aids to ethical reflection and guidance for clinicians dealing with these vulnerable families. They demonstrate the value of empirical data in the philosophical debate.

McHugh K. Neuroimaging in non-accidental head injury: if, when, why and how. *Clin Radiol* 2005; 60(7):826-7; author reply 827-8.

McInnes RJ, Stone DH. The process of implementing a community-based peer breast-feeding support programme: the Glasgow experience. *Midwifery* 2001; 17(1):65-73.

Abstract: AIM: to document the process of implementing and maintaining a community-based peer-support programme. DESIGN AND SETTING: a community-based study located in a socio-economically disadvantaged housing estate on the outskirts of Glasgow. PARTICIPANTS: pregnant women residing in a target postcode area. INTERVENTION: a programme of peer counselling and support for breast feeding, comprising antenatal and postnatal home visits over a period of three years. IMPLICATIONS FOR PRACTICE: peer support may provide an acceptable and appropriate role model for breast-feeding mothers. However, further research is required on other influential factors such as the social network and the impact of this programme on the peer supporter. CONCLUSIONS: despite a low prevalence of breast feeding, initiating and maintaining peer breast-feeding support was possible. Peer support appeared to be acceptable to mothers and health professionals. Study mothers spoke enthusiastically of the intervention and mentioned increased confidence and self-esteem.

McIntosh JE. Thought in the face of violence: a child's need. *Child Abuse Negl* 2002; 26(3):229-41.

Abstract: OBJECTIVE: This article provides a clinical perspective on the combined impacts on children of spousal violence in the home and the absence of attuned parental thought that accompanies it. METHODS: This article takes the form of a commentary, drawing on clinical case studies and research literature to illustrate the child's experience of "unthinking," nonreflective parental states of mind, from the point of witnessing violence through to contact arrangements post-separation. Parallel dynamics and impacts are discussed with caregiving and legislative systems. RESULTS: The article suggests that "unthinking" states of mind in parents can be as damaging for a child as the overt witnessing and experiencing of violence. CONCLUSIONS: The prevention or early overturning of unthinking states of mind, in and out of the home, greatly influences the nature of a child's recovery from domestic violence.

McKay MM, Atkins MS, Hawkins T, Brown C, Lynn CJ. Inner-city African American parental involvement in children's schooling: racial socialization and social support from the parent community. *Am J Community Psychol* 2003; 32(1-2):107-14.

Abstract: Parents (n = 161) and teachers (n = 18) from an urban elementary school serving primarily African American children completed questionnaires regarding racial socialization, social support, and involvement in activities that support youth educational achievement at home and school. Parental reports of racism awareness, and contact with school staff were significantly correlated with parent reports of at-home involvement and at-school involvement. Parent reports of social support from the parent community were significantly related to at-home involvement only. Relative to teacher reports, parents reported more formal contacts with school staff, and higher levels of racism awareness, religiosity, and African American cultural pride. Teachers and parents agreed on school climate and parental levels of at-home and at-school involvement. The results suggest that racial socialization processes are related to parent involvement in children's schooling and that increased efforts are needed to bridge a cultural gap between parents and teachers in inner-city communities.

McKee TE, Harvey E, Danforth JS, Ulaszek WR, Friedman JL. The relation between parental coping styles and parent-child interactions before and after treatment for children with ADHD and oppositional behavior. *J Clin Child Adolesc Psychol* 2004; 33(1):158-68.

Abstract: This study examined the relation between parental coping styles, discipline, and child behavior before and after participating in a parent training program for parents of children with Attention-Deficit/Hyperactivity Disorder (ADHD) and oppositional behavior. For mothers, use of more maladaptive and less adaptive coping styles was related to more self-reported lax and overreactive discipline, more observed coercive parenting, and more observed

child misbehavior prior to parent training. No significant relations were found for mothers following parent training after controlling for pretreatment variables. For fathers, use of more maladaptive and less adaptive coping styles was related to self-reported lax discipline before and after parent training. Contrary to prediction, fathers who reported less seeking support and adaptive-focused coping showed the most improvement in their children's behavior. Most results remained significant after controlling for self-reported depression. Implications for improving parent training research and programs were discussed.

McKeever P, Miller KL. Mothering children who have disabilities: a Bourdieusian interpretation of maternal practices. *Soc Sci Med* 2004; 59(6):1177-91. Abstract: In the last three decades, mothers of children who have chronic illnesses or disabilities have been studied extensively. With some notable exceptions, most research has overlooked the socio-political context of disability and has interpreted maternal behaviours and feelings in negative or psychopathological terms. In this paper we report the results of using Pierre Bourdieu's central concepts to reanalyse three independent qualitative studies focused on mothers' accounts of raising children with severe disabling conditions. We illustrate the logic of mothers' practices and conclude that they represent strategic manipulations of accessible bodily, cultural and symbolic capital consistent with the 'rules of the game' across multiple fields. Mothers struggled to establish and maintain the personhood and value of their children, and to obtain resources within a broader context of body normativeness, exclusion and inequity. This Bourdieusian rendering of the logic of maternal practices has important implications for research and paediatric practices.

McKenzie B, Bacon B. Parent education after separation: results from a multi-site study on best practices. *Can J Commun Ment Health* 2002; (4 Suppl):73-88. Abstract: Although parent education after separation in Canada is relatively new, most provinces and territories now have some type of program that provides separating parents with information on their children's needs, co-parenting options, and strategies for improving communication. A 1999-2000 survey of parents in 10 such program sites throughout Canada: (a) demonstrates a high level of parent satisfaction with the programs, (b) chronicles benefits related to reduced conflict and improved child well-being 3 to 4 months following program attendance, and (c) identifies several implications for best practices. Results of this study suggest that parent education is but one program within a network of services needed to support both parents and children after separation.

McMahon SD, Grant KE, Compas BE, Thurm AE, Ey S. Stress and psychopathology in children and

adolescents: is there evidence of specificity? *J Child Psychol Psychiatry* 2003; 44(1):107-33. Abstract: Research on the relations between specific stressors and specific psychological outcomes among children and adolescents is reviewed. Specificity, the notion that particular risk factors are uniquely related to particular outcomes is discussed from a theoretical perspective, and models of specificity are described. Several domains of stressors are examined from a specificity framework (e.g., exposure to violence, abuse, and divorce/marital conflict) in relation to broad-band outcomes of internalizing and externalizing symptoms. Studies that tested for specificity conducted within the past 15 years are examined, and definitional problems are highlighted. Little evidence for specificity was found. Methodological problems in the literature and the lack of theory-driven specificity research are discussed, and directions for future research are identified.

McMurray A. Domestic violence: conceptual and practice issues. *Contemp Nurse* 2005; 18(3):219-32. Abstract: This article analyses the conceptual issues surrounding domestic violence against women, including the lack of clarity in identifying accurate prevalence rates, and the affect of domestic violence on other family members. Research conducted in Australia and overseas provides an evidence base for the contention that violence against women is a serious problem for healthcare and society, and should be addressed comprehensively in both the healthcare and socio-legal context to protect the woman and the family. It is argued that solutions to the problem rely on knowledge and understanding of gender relations, cultural factors, the psychology of intimate partner attachments and the socio-legal system, particularly for separating couples. Recommendations for best practice in helping victims of violence are provided.

McNally RJ, Clancy SA, Schacter DL. Directed forgetting of trauma cues in adults reporting repressed or recovered memories of childhood sexual abuse. *J Abnorm Psychol* 2001; 110(1):151-6. Abstract: An item-cuing directed forgetting task was used to investigate whether women reporting repressed (n = 13) or recovered (n = 13) memories of childhood sexual abuse (CSA) exhibit an avoidant encoding style (and resultant impaired memory) for trauma cues relative to women reporting no CSA experience (n = 15). All participants viewed intermixed trauma (e.g., molested), positive (e.g., confident), and categorized neutral (e.g., mailbox) words on a computer screen and were instructed either to remember or to forget each word. The results provided no support for the hypothesis that people reporting either repressed or recovered memories of CSA are especially adept at forgetting words related to trauma. These groups recalled words they were instructed to remember more often than words they were instructed to forget regardless of whether they were trauma related.

McNaughton DB. Nurse home visits to maternal-child clients: a review of intervention research. *Public Health Nurs* 2004; 21(3):207-19. Abstract: Home visiting has been considered a promising strategy for addressing the multiple needs of families at risk. Research reviews are a valuable resource for researchers, policymakers, and practitioners who develop and support new home-visiting interventions. This review examines 13 research studies published between the years of 1980 and 2000 that test the effectiveness of home-visiting interventions using professional nurses as home visitors. Findings indicate that a wide range of client problems are addressed during home visits using a variety of nursing interventions. Missing from most of the reports is a clear theoretical link between the client problem addressed, the nursing intervention, and target outcomes. About half of the studies were successful in achieving desired outcomes. Future research should be directed by middle-range practice theory, clearly explicate the nursing intervention being tested, use power analysis to determine sample size, and report reliability and validity of dependent variable measures with culturally diverse samples.

McNeil-Haber FM. Ethical considerations in the use of nonerotic touch in psychotherapy with children. *Ethics Behav* 2004; 14(2):123-40. Notes: GENERAL NOTE: KIE: 35 refs. GENERAL NOTE: KIE: KIE Bib: patient care/minors; professional patient relationship Abstract: Although touch frequently occurs in psychotherapy with children, there is little written on the ethical considerations of therapeutic touch. Because physical contact does occur, therapists must consider if, how, and when it is used, for both their clients' safety and their own. In this review, I further develop the issues suggested by Aquino and Lee (2000) in the use of nurturing touch in therapy by considering many types of touch that occur in psychotherapy with children; the possible positive role of touch; clients' perception of touch in therapy; considerations related to the therapist, the child's safety, and any history of abuse in the child's and family's background; and other practical considerations. I list guidelines.

McNicholas J, Collis GM. Children's representations of pets in their social networks. *Child Care Health Dev* 2001; 27(3):279-94. Abstract: OBJECTIVES: To develop a child-friendly methodology to study children's representations of social support available from their personal relationships; and to examine children's representations of support from their pets compared to support from human relationships. DESIGN: Participants were 22 year-3 primary school children aged 7-8 years. They were asked to list all the people and animals important to them and then to select a 'top 10' of most special relationships. Using a story-based methodology, children were asked who from their 'top 10' they would

turn to if they were the child in the story. RESULTS: Consistency in the data indicated that the children could reliably discriminate between different relationships in terms of the support functions they serve. Pets were often ranked higher than certain kinds of human relationship, and they featured prominently as providers of comfort, esteem support and confidants for a secret. Confidence in these findings is gained through pets not being nominated for functions they could not realistically perform.

McPherson ML, Lairson DR, Smith EO, Brody BA, Jefferson LS. Noncompliance with medical follow-up after pediatric intensive care. *Pediatrics* 2002; 109(6):e94.

Abstract: OBJECTIVES: To describe the medical follow-up ordered, the health care utilization, the appointment compliance, and the risk factors associated with noncompliance in patients who are discharged after a pediatric intensive care unit (PICU) stay. METHODS: A prospective, analytic, cohort study of 111 critically ill children, age 1 day to 16 years, who were admitted to a 30-bed PICU in an urban, tertiary-care, pediatric teaching hospital compared children who were compliant with medical follow-up with those who were not. The main outcomes measured were emergent and unscheduled physician visits during the first 6 weeks after hospital discharge; compliance with ordered medical follow-up after hospital discharge; and comparisons of socioeconomic, demographic, and medical need factors between compliant and noncompliant children. Discharge orders for follow-up appointments with general pediatricians and subspecialists were collected from the chart at hospital discharge. Patients were contacted after hospital discharge to determine whether and when they received medical follow-up; 28% were found to be noncompliant. Risk factors associated with noncompliance were evaluated. Emergent and unscheduled physician visits were tracked during the first 6 weeks after hospital discharge. RESULTS: Lack of follow-up orders at hospital discharge did not affect the frequency of emergent visits. Children fell into 2 groups: those who were 100% compliant and those with < or =67% compliance. No socioeconomic or demographic risk factors could be identified between the 2 groups. Compared with the 100% compliant patients, patients who were compliant with < or =67% of appointments were more severely ill, as defined by higher peak pediatric risk of mortality scores during their PICU stay (11.5 vs 8.4), longer PICU length of

stays (10.1 days vs 4.6 days), and longer hospital length of stays (25.5 days vs 14 days). Most predictive of noncompliance was the number of medical appointments ordered by physicians. Patients with 3 or more appointments were less likely to be compliant with follow-up. After hospital discharge, children were more likely to visit a primary care physician compared with a subspecialist (95% vs 82%). When patients were ordered to see a specialist, scheduled appointments were much better attended than the recommended appointments (92% vs 67%). CONCLUSIONS: Lack of ordered medical follow-up did not affect emergent visits. In this group of critically ill children, a significant percentage (28%) did not receive timely medical follow-up. No socioeconomic or demographic risk factors were identified in noncompliant children. However, severity of illness (higher peak pediatric risk of mortality score, longer PICU stay, and longer hospital stay) and the number of follow-up appointments ordered were predictors of noncompliance. Potential exists for implementing strategies to improve compliance in identified populations.

Meadow W, Frain L, Ren Y, Lee G, Soneji S, Lantos J. Serial assessment of mortality in the neonatal intensive care unit by algorithm and intuition: certainty, uncertainty, and informed consent. *Pediatrics* 2002; 109(5):878-86.

Notes: GENERAL NOTE: KIE: 40 refs. GENERAL NOTE: KIE: KIE Bib: allowing to die/infants; patient care/minors

Abstract: OBJECTIVES: Does predictive power for outcomes of neonatal intensive care unit (NICU) patients get better with time? Or does it get worse? We determined the predictive power of Score for Neonatal Acute Physiology (SNAP) scores and clinical intuitions as a function of day of life (DOL) for newborn infants admitted to our NICU. METHODS: We identified 369 infants admitted to our NICU during 1996-1997 who required mechanical ventilation. We calculated SNAP scores on DOL 1, 3, 4, 5, 7, 10, 14, 21, 28, and weekly thereafter until either death or extubation. We also asked nurses, residents, fellows, and attendings on each day of mechanical ventilation: "Do you think this child is going to live to go home to their family, or die before hospital discharge?" RESULTS: Two thousand twenty-eight SNAP scores were calculated for 285 infants. On DOL 1, SNAP for nonsurvivors (24 +/- 8.7 [standard

deviation]) was significantly higher than SNAP for survivors (13 +/- 6.1). However, this difference diminished steadily and by DOL 10 was no longer statistically significant (12.7 +/- 4.9 vs 10.0 +/- 4.8). On each NICU day, at all ranges of SNAP scores, there were at least as many infants who would ultimately survive as would die. Consequently, the positive predictive value of any SNAP value for subsequent mortality was <0.5 on all NICU days. Prediction profiles were obtained for 230 ventilated infants reflecting over 11 000 intuitions obtained on 2867 patient days. One hundred fifty-seven (81%) of 192 survivor profiles displayed consistent accurate prediction profiles--at least 90% of their NICU ventilation days were characterized by 100% prediction of survival. Twenty-five (13%) of 192 surviving infants survived somewhat unexpectedly; that is, after at least 1 day characterized by at least 1 estimate of "death." Thirty-three (60%) of the 55 nonsurvivors died before DOL 10. Eighty-two percent of the prediction profiles for these early dying infants were homogeneous, dismal, and accurate. Twenty-two (40%) of the 55 nonsurvivors died after DOL 10. Seventeen (78%) of these 22 late-dying infants were predicted to live by many observers on many hospital days. Sixty-one (30%) of 230 profiled patients had at least 1 NICU day characterized by at least 1 prediction of death; 26/61 (43%) of these patients were incorrectly predicted; that is, they survived. Seventeen infants who were predicted to die during but survived nonetheless were assessed neurologically at 1 year. Fourteen (82%) of these 17 were not neurologically normal--8 were clearly abnormal, 1 suspicious, and 5 had died. CONCLUSIONS: If absolute certainty about mortality is the only criterion that can justify a decision to withhold or withdraw life-sustaining treatment in the NICU, these data would make such decisions difficult on the first day of life, and increasingly problematic thereafter. However, if we acknowledge that medicine is inevitably an inexact science and that clinical predictions can never be perfect, we can ask the more interesting question of whether good but less-than-perfect predictions of imprecise but ethically relevant clinical outcomes can still be useful. We think that they can--and that they must.

Meadows LM, Thurston WE, Lackner S. Wealth study: women's reports of childhood abuse. *Health Care Women Int* 2001; 22(5):439-54.

Abstract: Most samples of adult women will contain a significant proportion who have been or are currently in abusive relationships. While past research has linked childhood abuse of girls to adult health concerns, little is known about the process through which women retrospectively reconcile these experiences. This article reports on data collected in an ongoing project on midlife women's health. Twenty-seven of 50 urban, middle-class participants in this phase of the project reported childhood abuse experiences. In the analysis, several aspects of these experiences were identified:

definitions of abuse; recontextualizing abuse; responsibility for abuse; abuse avoidance; and experiences of multiple abuse. The women's discourse reflected a number of ideologies that provide a context in which women negotiate their understandings of these childhood experiences. This article provides insight into our understanding of abuse. It addresses the fundamental issue of promoting a worldview that precludes child abuse while leaving adult survivors with options for "moving on."

Meadows M. Drug research and children. *FDA Consum* 2003; 37(1):12-7.

Mechanic D. Disadvantage, inequality, and social policy. *Health Aff (Millwood)* 2002; 21(2):48-59. Abstract: Eliminating disparities in health is a primary goal of the federal government and many states. Our overarching objective should be to improve population health for all groups to the maximum extent. Ironically, enhancing population health and even the health of the disadvantaged can conflict with efforts to reduce disparities. This paper presents data showing that interventions that offer some of the largest possible gains for the disadvantaged may also increase disparities, and it examines policies that offer the potential to decrease disparities while improving population health. Enhancement of educational attainment and access to health services and income support for those in greatest need appear to be particularly important pathways to improved population health.

Medora NP, Wilson S, Larson JH. Attitudes toward parenting strategies, potential for child abuse, and parental satisfaction of ethnically diverse low-income U.S. mothers. *J Soc Psychol* 2001; 141(3):335-48. Abstract: Among a sample of 176 low-income mothers from 3 ethnic groups in the United States, the authors investigated ethnic differences in attitudes toward preferred parenting strategies, or styles; ethnic differences in the potential for child abuse; and the relationship between parenting strategies, the potential for child abuse, and parental satisfaction. They distributed the Maternal Reactions to Child's Deviant Behavior subscale (K. M. Rickard, W. Graziano, & R. Forehand, 1984), a shortened version of the Child Abuse Potential Inventory (CAPI; J. S. Milner & R. C. Wimberley, 1979), and a Parental Satisfaction Scale (N. P. Medora, S. M. Wilson, & J. Larson, 1996) to the participants. The results indicated no significant ethnic differences in preferred parenting styles. Mothers from all 3 ethnic groups ranked praise and reasoning as the 1st and 2nd preferred parenting strategies. There were no ethnic differences in the perceived potential for child abuse. Parental satisfaction was negatively related to 2 of the CAPI subscales--Loneliness and Problems. The parenting strategy reasoning was positively correlated with parental satisfaction.

Meel BL. Incidence and patterns of violent and/or traumatic deaths between 1993 and 1999 in the Transkei region of South Africa. *J Trauma* 2004; 57(1):125-9. Abstract: BACKGROUND: Incidence and patterns of violent and/or traumatic deaths among 4,525 victims over a 7-year period in the Transkei region of South Africa were investigated. METHOD: Retrospective review and analysis was performed of all medicolegal autopsies (n = 6,181) between January 1993 and December 1999, of which 4,525 were violent or traumatic deaths. RESULTS: During the 7-year period (January 1993-December 1999), violent and/or traumatic deaths in the Transkei region accounted for an average annual rate of 162 per 100,000 of the population. The common causes of deaths per 100,000 of population per year were as follows: motor vehicle collisions, 63; firearm injuries, 43; stab wounds, 32; and blunt trauma, 24. Male subjects outnumbered female subjects by a 3.3:1 ratio. The murder rate in female subjects was 18 per 100,000 population. The murder rate in this area increased from 94 per 100,000 in 1993 to 121 in 1999. Nearly 50% of the violent and/or traumatic deaths occurred in the 21- to 40-year age group. There has been an increase in nontraumatic deaths such as hanging (1.5 times) and poisoning (5 times). CONCLUSION: The average annual incidence of violent and/or traumatic deaths in the Transkei region of South Africa is 162 per 100,000 population. Firearm-related deaths, at 43 per 100,000 of the population per year, have contributed substantially to this high incidence. This is a major cause of concern.

Meel BL. Mortality of children in the Transkei region of South Africa. *Am J Forensic Med Pathol* 2003; 24(2):141-7.

Abstract: This study attempted to unfold, perhaps for the first time, the problem of childhood mortality resulting from trauma in the Eastern Cape Province of South Africa. This study was carried out in the Umtata and Ngqeleni magisterial districts, which have a combined population of about 400,000. Most people there have very few resources and have historically relied on money repatriated by migrant workers. In the Transkei region, unemployment is at a very high level: 48.5%. Assault on children is very common in this region, and this may result in death. The aim of this study was to establish the state of deaths resulting from pediatric trauma, and to formulate recommendations that could probably help prevent or reduce these deaths. The objective was to gather epidemiologic information on the victims of pediatric trauma. The study was designed as a descriptive study, using reviews of traumatic deaths in pediatric age groups during the period January 1993 to December 1999. This study was carried out on cases that were brought to the medicolegal laboratory at Umtata General Hospital, Umtata, in the Transkei region of the Eastern Cape Province, South Africa. There were 6181 autopsies conducted from 1993 to 1999. All the medicolegal autopsies were divided into two groups:

pediatric (15 years of age or younger) and adult (older than 15 years). Of the autopsies, 89.4% (n = 5587) were in the adult group, and 10.6% (n = 594) were in the pediatric group. Of the pediatric deaths, 64% (n = 383) were related to trauma. The highest numbers were in the 11- to 15-year (n = 146, 38%) and the 6- to 10-year (n = 135, 34%) age groups. Of the children who died of trauma, 112 (28%) were aged 0 to 5 years. Unintentional injuries from motor vehicle accidents were the leading cause of death (59%), whereas intentional injuries (41%) were associated with murder. Nearly a quarter (22%) of pediatric traumatic deaths were due to penetrating injuries: stab (12%) and gunshot (10%) wounds. Most of the pediatric deaths occurred during the festive months of December, January, and April; the death toll during these months was three to four times higher than in the rest of the year. It was concluded that 64% of pediatric deaths in the Transkei region were the result of trauma. This represents 1 pediatric trauma death for every 10 adult trauma deaths. Forty-one percent of the child trauma deaths were due to intentional injuries, usually murder. It is recommended that the government set targets and put into place strategies for the reduction of pediatric deaths due to trauma. The different deaths so called "rule of reversal" could be considered as an indicator of social health.

Mehta PD, Neale MC, Flay BR. Squeezing interval change from ordinal panel data: latent growth curves with ordinal outcomes. *Psychol Methods* 2004; 9(3):301-33. Abstract: A didactic on latent growth curve modeling for ordinal outcomes is presented. The conceptual aspects of modeling growth with ordinal variables and the notion of threshold invariance are illustrated graphically using a hypothetical example. The ordinal growth model is described in terms of 3 nested models: (a) multivariate normality of the underlying continuous latent variables ( $y_t$ ) and its relationship with the observed ordinal response pattern ( $Y_t$ ), (b) threshold invariance over time, and (c) growth model for the continuous latent variable on a common scale. Algebraic implications of the model restrictions are derived, and practical aspects of fitting ordinal growth models are discussed with the help of an empirical example and Mx script (M. C. Neale, S. M. Boker, G. Xie, & H. H. Maes, 1999). The necessary conditions for the identification of growth models with ordinal data and the methodological implications of the model of threshold invariance are discussed.

Meier P, Schmitz F, Wiedemann P. Vitrectomy for pre-macular hemorrhagic cyst in children and young adults. *Graefes Arch Clin Exp Ophthalmol* 2005; 243(8):824-8. Abstract: **BACKGROUND:** A pre-macular accumulation of blood is termed a hemorrhagic macular cyst and may be found both in eyes with Terson's syndrome and in shaken baby syndrome. In this study, we report on our experience and results of

vitrectomy for treatment of pre-macular hemorrhagic cyst in eyes of patients suffering from Terson's syndrome and shaken baby syndrome. **PATIENTS AND METHODS:** Between November 1995 and May 2003 seven eyes of six children underwent vitrectomy for pre-macular hemorrhagic cyst. Patients' age ranged from 5 months to 17 years. Indication for vitrectomy was pre-macular hemorrhagic cyst in eyes with Terson's syndrome (n=5) and shaken baby syndrome (n=2). During vitrectomy, rhexis of internal limiting membrane was performed. Four children received intensive orthoptic treatment postoperatively. **RESULTS:** All eyes in our series showed a submembranous localization of pre-macular hemorrhagic cyst. The results of electron microscopic examination showed that the excised anterior walls contain internal limiting membrane. In all eyes improvement of the anatomic situation and of visual acuity was achieved. Duration of follow-up ranged from 6 months to 5 years. **CONCLUSIONS:** Vitrectomy for hemorrhagic macular cyst in children is a safe and effective alternative to observation, offering visual rehabilitation, especially if amblyopia has developed or if both eyes are affected. If a hemorrhagic macular cyst is encountered, its complete removal is recommended to prevent development of proliferative vitreoretinopathy.

Meller K, Passero C. The cold truth. *Pediatr Nurs* 2004; 30(1):41-2.

Mellins CA, Smith R, O'Driscoll P *et al.* High rates of behavioral problems in perinatally HIV-infected children are not linked to HIV disease. *Pediatrics* 2003; 111(2):384-93.

Notes: **CORPORATE NAME:** NIH NIAID/NICHD/NIDA-Sponsored Women and Infant Transmission Study Group  
**Abstract: OBJECTIVE:** Descriptive studies and clinical reports have suggested that human immunodeficiency virus (HIV)-positive children are at risk for behavioral problems. Inadequate control groups and sample sizes have limited the ability of investigators to consider multiple influences that place HIV-positive children at risk for poor behavioral outcomes. We examined the unique and combined influences of HIV, prenatal drug exposure, and environmental factors on behavior in children who were perinatally exposed to HIV. **METHODS:** Participants included 307 children who were born to HIV-positive mothers (96 HIV infected and 211 seroreverters) and enrolled in a natural history, longitudinal study of women to infant HIV transmission. Caregivers completed parent behavioral rating scales, beginning when the children were 3 years old. Data were also collected on prenatal drug exposure; child age, gender, and ethnicity; caregiver relationship to child; and birth complications. **RESULTS:** Multivariate analyses comparing the HIV-infected children with perinatally exposed but uninfected children from similar backgrounds failed to

- find an association between either HIV status or prenatal drug exposure and poor behavioral outcomes. The strongest correlates of increased behavioral symptoms were demographic characteristics. CONCLUSIONS: This study suggests that although a high prevalence of behavioral problems does exist among HIV-infected children, neither HIV infection nor prenatal drug exposure is the underlying cause. Rather, other biological and environmental factors are likely contributors toward poor behavioral outcomes.
- Melton GB. Mandated reporting: a policy without reason. *Child Abuse Negl* 2005; 29(1):9-18.
- Menard CB, Bandeen-Roche KJ, Chilcoat HD. Epidemiology of multiple childhood traumatic events: child abuse, parental psychopathology, and other family-level stressors. *Soc Psychiatry Psychiatr Epidemiol* 2004; 39(11):857-65. Abstract: BACKGROUND: Multiple family-level childhood stressors are common and are correlated. It is unknown if clusters of commonly co-occurring stressors are identifiable. The study was designed to explore family-level stressor clustering in the general population, to estimate the prevalence of exposure classes, and to examine the correlation of sociodemographic characteristics with class prevalence. METHOD: Data were collected from an epidemiological sample and analyzed using latent class regression. RESULTS: A six-class solution was identified. Classes were characterized by low risk (prevalence=23%), universal high risk (7%), family conflict (11%), household substance problems (22%), non-nuclear family structure (24%), parent's mental illness (13%). CONCLUSIONS: Class prevalence varied with race and welfare status, not gender. Interventions for childhood stressors are person-focused; the analytic approach may uniquely inform resource allocation.
- Menick DM. [Problems of child sexual abuse in Africa or the imbroglio of a double paradox: the example of Cameroon]. *Child Abuse Negl* 2001; 25(1):109-21. Abstract: OBJECTIVE: This study has investigated the prevalence of sexual abuse cases in Cameroon (Africa) and approached the way these cases are solved. METHOD: 405 medical certificates have been reviewed within a three years period. RESULTS: Over 405 medical certificates, 19 cases of sexual abuse have been identified. All the victims were girls. The great majority of them were aged 10-14 (57.9%) and 15-19 (31.6%). The sexual assaults have been perpetrated out of the family. CONCLUSION: The results show evidence of sexual abuse cases in Africa. Friendly adjustments by private contracts and family interventions with financial amends for the parents of the victims are often preferred to the court of justice, because of poverty, cultural pressures and judicial injunctions.
- Menick DM. [Sexual abuse at schools in Cameroon: results of a survey-action program in Yaounde]. *Med Trop (Mars)* 2002; 62(1):58-62. Abstract: The purpose of this questionnaire-based study was to determine the incidence of sexual abuse in schools in Yaounde, Cameroon, to assess the extent of teacher involvement in such acts and to provide children an opportunity to come forward with their experiences. The author hypothesized that the number of sexual abuse victims was increasing and that the most frequent abusers were teachers, school staff, and classmates. To check this hypothesis, a total of 1710 questionnaires were sent to 10 public and private secondary schools between January 4 and April 30, 1999. The response rate was 98.7%. A total of 269 students reported being sexual abused before the age of 16 for an overall incidence of 15.9%. There were 74 boys (27.5%) and 195 girls (72.5%) with a mean age 11.6 years (range 4 to 15 years) at the time of abuse. Sexual abuse involved rape in 38.7% of cases, fondling in 54.6% and pornographic scenes in 6.7%. Of the 274 sexual abusers identified, 86.5% were men and 13.5% were women. Sexual abuse took place within the family in 31.4% of cases and outside the family setting 68.6%. Sexual abuse occurred in a school setting in approximately 15% of cases and involved classmates in approximately 30%. The alleged extrafamilial abusers were teachers in 7.9% of cases and tutors in 7.6%. Survey data supports the working hypothesis of this study and warrants implementation of a program to prevent sexual abuse in schools.

- Mercer J. Coercive restraint therapies: a dangerous alternative mental health intervention. *MedGenMed* 2005; 7(3):6. Abstract: Physicians caring for adopted or foster children should be aware of the use of coercive restraint therapy (CRT) practices by parents and mental health practitioners. CRT is defined as a mental health intervention involving physical restraint and is used in adoptive or foster families with the intention of increasing emotional attachment to parents. Coercive restraint therapy parenting (CRTP) is a set of child care practices adjuvant to CRT. CRT and CRTP have been associated with child deaths and poor growth. Examination of the CRT literature shows a conflict with accepted practice, an unusual theoretic basis, and an absence of empirical support. Nevertheless, CRT appears to be increasing in popularity. This article discusses possible reasons for the increase, and offers suggestions for professional responses to the CRT problem.

Mercer JA. The Protestant child, adolescent, and family. *Child Adolesc Psychiatr Clin N Am* 2004; 13(1):161-81, ix.

Abstract: This article addresses Protestant Christianity as an often-overlooked but significant factor in clinical work with children and adolescents. Noting the wide range of beliefs and practices among Protestants, the article identifies key tenets of Protestant faith that shape the worldviews of children, adolescents, and their families. Clinical implications of these beliefs are explored, with particular attention to three potentially psychopathologic features: the religious legitimization of child maltreatment; paranormal, direct experiences of the divine through unusual perceptions such as trance states or visions deemed normal within their religious context but that may also evidence serious pathology; and sexuality issues of particular significance for adolescents. Research suggests that Protestant beliefs also constitute resources for clinical work because they appear to be protective factors in relation to depression, avoidance of high-risk behaviors, and other measures of resiliency among adolescents. Clinicians who do not take the Protestant Christian family's religious/spiritual worldview into consideration in case formulation risk misunderstanding or alienating them from treatment. The article concludes with suggestions for collaboration.

Mermin J, Lule J, Ekwaru JP *et al*. Cotrimoxazole prophylaxis by HIV-infected persons in Uganda reduces morbidity and mortality among HIV-uninfected family members. *AIDS* 2005; 19(10):1035-42.

Abstract: **BACKGROUND:** The effect of cotrimoxazole prophylaxis taken by persons with HIV on community health and antimicrobial resistance is unknown. **OBJECTIVE:** To assess the effect of cotrimoxazole prophylaxis taken by persons with HIV on morbidity, mortality, and antimicrobial resistance of diarrheal pathogens infecting their HIV-negative family members. **DESIGN:** Prospective cohort in rural Uganda. **METHODS:** A total of 879 persons with HIV and 2771 HIV-negative family members received weekly home-visits. After 5 months, persons with HIV received daily cotrimoxazole prophylaxis and households were followed for an average of 17 additional months. **FINDINGS:** During the study, 224 participants with HIV (25%) and 29 household members (1%) died. Mortality among HIV-negative family members < 10 years old was 63% less during the cotrimoxazole period than before [hazard ratio, 0.37; 95% confidence interval (CI), 0.14-0.95; P = 0.04]. Malaria among family members was less common during cotrimoxazole treatment [incidence rate ratio (IRR), 0.62; CI, 0.53-0.74; P < 0.0001], as were diarrhea (IRR, 0.59; CI, 0.45-0.76; P = 0.0001),

and hospitalizations (IRR, 0.57; CI, 0.36-0.92; P = 0.02). Death of a parent with HIV was associated with a threefold increase in mortality among HIV-negative children < 10 years old (hazard ratio, 2.9; CI, 1.1-8.1; P = 0.04). Of 134 bacterial isolates from family members before cotrimoxazole treatment, 89 (66%) were resistant to cotrimoxazole; of 75 recovered during cotrimoxazole treatment, 54 (72%) were resistant (P = 0.41). **INTERPRETATION:** Cotrimoxazole prophylaxis taken by persons with HIV was associated with decreased morbidity and mortality among family members. Antimicrobial resistance among diarrheal pathogens infecting family members did not increase. Concerns regarding the spread of bacterial resistance should not impede implementation of cotrimoxazole programs.

Mermin J, Lule J, Ekwaru JP *et al*. Effect of co-trimoxazole prophylaxis on morbidity, mortality, CD4-cell count, and viral load in HIV infection in rural Uganda. *Lancet* 2004; 364(9443):1428-34.

Abstract: **BACKGROUND:** Prophylaxis with co-trimoxazole (trimethoprim-sulphamethoxazole) is recommended for people with HIV infection or AIDS but is rarely used in Africa. We assessed the effect of such prophylaxis on morbidity, mortality, CD4-cell count, and viral load among people with HIV infection living in rural Uganda, an area with high rates of bacterial resistance to co-trimoxazole. **METHODS:** Between April, 2001, and March, 2003, we enrolled, and followed up with weekly home visits, 509 individuals with HIV-1 infection and their 1522 HIV-negative household members. After 5 months of follow-up, HIV-positive participants were offered daily co-trimoxazole prophylaxis (800 mg trimethoprim, 160 mg sulphamethoxazole) and followed up for a further 1.5 years. We assessed rates of malaria, diarrhoea, hospital admission, and death. **FINDINGS:** Co-trimoxazole was well tolerated with rare (<2% per person-year) adverse reactions. Even though rates of resistance in diarrhoeal pathogens were high (76%), co-trimoxazole prophylaxis was associated with a 46% reduction in mortality (hazard ratio 0.54 [95% CI 0.35-0.84], p=0.006) and lower rates of malaria (multivariate incidence rate ratio 0.28 [0.19-0.40], p<0.0001), diarrhoea (0.65 [0.53-0.81], p<0.0001), and hospital admission (0.69 [0.48-0.98], p=0.04). The annual rate of decline in CD4-cell count was less during prophylaxis than before (77 vs 203 cells per microL, p<0.0001), and the annual rate of increase in viral load was lower (0.08 vs 0.90 log(10) copies per mL, p=0.01). **INTERPRETATION:** Daily co-trimoxazole prophylaxis was associated with reduced morbidity and mortality and had beneficial effects on CD4-cell count and viral load. Co-trimoxazole prophylaxis is a readily available, effective intervention for people with HIV infection in Africa.

Merry S, McDowell H, Hetrick S, Bir J, Muller N. Psychological and/or educational interventions for the

prevention of depression in children and adolescents. Cochrane Database Syst Rev 2004; (1):CD003380. Abstract: BACKGROUND: Depression is the fourth most important disease in the estimation of the burden of disease Murray 1996 and is a common problem with prevalence rates estimated to be as high as 8% in young people. Depression in young people is associated with poor academic performance, social dysfunction, substance abuse, suicide attempts, and completed suicide (NHMRC 1997). This has precipitated the development of programmes aimed at preventing the onset of depression. This review evaluates evidence for the effectiveness of these prevention programmes. OBJECTIVES: To determine whether psychological and/or educational interventions (both universal and targeted) are effective in reducing risk of depressive disorder by reducing depressive symptoms immediately after intervention or by preventing the onset of depressive disorder in children and adolescents over the next one to three years. SEARCH STRATEGY: The Cochrane Depression, Anxiety and Neurosis Group trials register (August 2002), MEDLINE (1966 to December Week 3 2002), EMBASE (1980 to January Week 2 2003), PsychInfo (1886 to January Week 2 2003) and ERIC (1985 to December 2002) were searched. In addition, conference abstracts, the reference lists of included studies, and other reviews were searched and experts in the field were contacted. SELECTION CRITERIA: Each identified study was assessed for possible inclusion by two independent reviewers based on the methods sections. The determinants for inclusion were that the trial include a psychological and/or educational prevention programme for young people aged 5 to 19 years-old, who did not meet DSM or ICD criteria for depression and/or did not fall into the clinical range on standardised, validated, and reliable rating scales of depression. DATA COLLECTION AND ANALYSIS: The methodological quality of the included trials was assessed by two independent reviewers according to a list of pre-determined criteria, which were based on quality ratings devised by Moncrieff and colleagues (Moncrieff 2001). Outcome data was extracted and entered into Revman 4.2. Means and standard deviations for continuous outcomes and number of events for dichotomous outcomes were extracted where available. For trials where the required data were not reported or could not be calculated, further details were requested from first authors. If no further details were provided, the trial was included in the review and described, but not included in the meta-analysis. Results were presented for each type of intervention: targeted or universal interventions; and educational or psychological interventions and if data were provided, by gender. Where possible data were combined in meta-analyses to give a treatment effect across all trials. Sensitivity analysis were conducted on studies rated as "adequate" or "high" quality, that is with a score over 22, based on the scale by Moncrieff et al (Moncrieff 2001). The presence of publication bias was

assessed using funnel plots. MAIN RESULTS: Studies were divided into those that compared intervention with an active comparison or placebo (i.e. a control condition that resembles the intervention being investigated but which lacks the elements thought to be active in preventing depression) and those that used a "wait-list" or no intervention comparison group. Only two studies fell into the former category and neither showed effectiveness although one study was inadequately powered to show a difference and in the other the "placebo" contained active therapeutic elements, reducing the ability to demonstrate a difference from intervention. Psychological interventions were effective compared with non-intervention immediately after the programmes were delivered with a significant reduction in scores on depression rating scales for targeted (standardised mean difference (SMD) of -0.26 and a 95% confidence interval (CI) of -0.40 to -0.13 ) but not universal interventions (SMD -0.21, 95% CI -0.48, 0.06), with a significant effect maintained on pooling data (SMD -0.26, 95% CI -0.36, -0.15). While small effect sizes were reported, these were associated with a significant reduction in depressive episodes. The overall risk difference after intervention translates to "numbers needed to treat" (NNT) of 10. The most effective study is the targeted programme by Clarke (Clarke 2001) where the initial effect size of -0.46 is associated with an initial risk difference of -0.22 and NNT 5. There was no evidence of effectiveness for educational interventions. Reports of effectiveness for boys and girls were contradictory. The quality of many studies was poor, and only two studies made allocation concealment explicit. Sensitivity analysis of only high quality studies did not alter the results significantly. The only analysis in which there was significant statistical heterogeneity was the sub-group analysis by gender where there was variability in the response to different programmes for both girls and boys. For the most part funnel plots indicate findings are robust for short term effects with no publication bias evident. There are too few studies to comment on whether there is publication bias for studies reporting long-term (12-36 month) follow-up. REVIEWER'S CONCLUSIONS: Although there is insufficient evidence to warrant the introduction of depression prevention programmes currently, results to date indicate that further study would be worthwhile. There is a need to compare interventions with a placebo or some sort of active comparison so that study participants do not know whether they are in the intervention group or not, to investigate the impact of booster sessions to see if effectiveness immediately after intervention can be prolonged, ideally for a year or longer, and to consider practical implementation of prevention programmes when choosing target populations. Until now most studies have focussed on psychological interventions. The potential effectiveness of educational interventions has not been fully investigated. Given the gender differences in prevalence, and the change in these that

occurs in adolescence with a disproportionate increase in prevalence rates for girls, it is likely that girls and boys will respond differently to interventions. Although differences have been reported in studies in this review the findings are contradictory and a more definitive delineation of gender specific responses to interventions would be helpful.

Mertin P, Mohr PB. Incidence and correlates of posttrauma symptoms in children from backgrounds of domestic violence. *Violence Vict* 2002; 17(5):555-67. Abstract: In recent years, evidence has emerged of the presence of posttrauma symptoms in children from backgrounds of domestic violence. The present study examined the incidence and correlates of posttrauma symptoms in 56 children of mothers who had been residents in women's shelters in Adelaide, South Australia. The most frequently endorsed symptoms among this sample of children were being troubled by distressing thoughts, conscious avoidance, hypervigilance, and sleep difficulties. Twenty percent of children met the criteria for a diagnosis of posttraumatic stress disorder (PTSD). Children meeting full PTSD criteria scored significantly higher on measures of anxiety, depression, and dissociation. Results support the use of a posttrauma framework for understanding the effects on children of living with domestic violence.

Metneki J, Puho E, Czeizel AE. Maternal diseases and isolated orofacial clefts in Hungary. *Birth Defects Res A Clin Mol Teratol* 2005; 73(9):617-23. Abstract: BACKGROUND: Isolated orofacial clefts (OFCs) are likely to be caused by gene-environment interaction; therefore, the objective of the current study was to evaluate the possible association between all maternal diseases during pregnancy and isolated cleft lip with or without cleft palate (CL+/-CP) and posterior cleft palate (PCP) in the offspring. METHODS: The database of the large population-based Hungarian Case-Control Surveillance of Congenital Abnormalities, 1980-1996, was evaluated. The database includes 1374 cases with isolated CL+/- CP and 601 with PCP, plus 38,151 matched population controls (without defects) and 20,868 patient controls with other defects. Data collection was based on prospective medical records, retrospective maternal data via a self-reported questionnaire, and home visits of nonresponding families. RESULTS: An increased risk for isolated CL+/- CP was found for children born to mothers with influenza, common cold, orofacial herpes, and gastroenteritis during pregnancy. Risk for isolated PCP was increased in children of mothers with influenza, sinusitis, and bronchitis. Among chronic maternal diseases, epilepsy and angina pectoris showed

a higher prevalence in the mothers of children born with isolated OFCs (cases). CONCLUSIONS: Some maternal diseases are risk factors for the pathogenesis of isolated OFCs. It is worth considering the prevention of possible harmful effects of influenza by vaccination during the expected epidemic period.

Metzger X. [Data aggregation in measuring inequalities and inequities in the health of populations]. *Rev Panam Salud Publica* 2002; 12(6):445-53. Abstract: OBJECTIVES: To compare how different degrees of data aggregation influence the measurement of health inequalities and health inequities within a population, and to assess the appropriateness of those different degrees of data aggregation in performing studies on inequalities and inequities. METHODS: As an example, we used data on the infant mortality rate in Costa Rica in 1973 and in 1984 and calculated measurements that are frequently used to quantify inequalities and inequities. RESULTS: According to our results, the inequality measures presented (except for those that were derived using regression models) are not sensitive to data aggregation by socioeconomic groups. However, when geographic areas are compared, more disaggregation of the data results in the measures indicating greater inequality. CONCLUSIONS: Our results show that some measures can vary widely depending on the level of data aggregation. It is thus crucial to know how to select these measures and also how to aggregate the data in a way that is consistent with the objectives of each study.

Meyer-Bahlburg HF. Child-adult sexual contact: terminology. *Arch Sex Behav* 2002; 31(2):157.

Meyers LA, Pourbohloul B, Newman ME, Skowronski DM, Brunham RC. Network theory and SARS: predicting outbreak diversity. *J Theor Biol* 2005; 232(1):71-81. Abstract: Many infectious diseases spread through populations via the networks formed by physical contacts among individuals. The patterns of these contacts tend to be highly heterogeneous. Traditional "compartmental" modeling in epidemiology, however, assumes that population groups are fully mixed, that is, every individual has an equal chance of spreading the disease to every other. Applications of compartmental models to Severe Acute Respiratory Syndrome (SARS) resulted in estimates of the fundamental quantity called the basic reproductive number  $R_0$ --the number of new cases of SARS resulting from a single initial case--above one, implying that, without public health intervention, most outbreaks should spark large-scale epidemics. Here we compare these predictions to the early epidemiology of SARS. We apply the methods of contact network epidemiology to illustrate that for a

- single value of R0, any two outbreaks, even in the same setting, may have very different epidemiological outcomes. We offer quantitative insight into the heterogeneity of SARS outbreaks worldwide, and illustrate the utility of this approach for assessing public health strategies.

Abstract: Court decisions concerning the life and death of patients become more and more frequent in the context of medical practice. One of the most controversial decisions in this area in recent years has been the decision of the Court of Appeal in Re A (Conjoined Twins: Medical Treatment), authorising the separation of conjoined twins. This paper will argue that the decision was flawed both on legal and moral grounds and that its potential implications for future cases are more far-reaching than the judgment itself suggests.
- Mick E, Biederman J, Pandina G, Faraone SV. A preliminary meta-analysis of the child behavior checklist in pediatric bipolar disorder. *Biol Psychiatry* 2003; 53(11):1021-7.  
Abstract: BACKGROUND: A possible explanation for the ongoing controversy surrounding pediatric bipolar disorder is that differences in assessment methodologies lead to conflicting results. One way to address methodological differences in assessment across studies is to use a single standardized assessment of psychopathology to calibrate the findings reported in different studies. To this end, we conducted a meta-analysis of several studies that have employed the Child Behavior Checklist in the assessment of children with a diagnosis of bipolar disorder. METHODS: MEDLINE was searched for all publications that utilized the Child Behavior Checklist in addition to structured diagnostic interviews to assess pediatric bipolar disorder. Random effects models were used to calculate combined estimates of Child Behavior Checklist clinical subscales. RESULTS: Children with bipolar disorder had scaled scores of >70 in the Aggression, Attention Problems, and Anxious/Depressed subscales of the Child Behavior Checklist. The Child Behavior Checklist was useful in distinguishing bipolar from attention-deficit/hyperactivity disorder subjects. CONCLUSIONS: While there was a significant heterogeneity in estimates between studies, a consistent pattern of elevations in inattention/hyperactivity, depression/anxiety, and aggression was identified.

- Mijanovich T, Weitzman BC. Which "broken windows" matter? School, neighborhood, and family characteristics associated with youths' feelings of unsafety. *J Urban Health* 2003; 80(3):400-15.  
Abstract: Young people's fears of victimization and feelings of unsafety constitute a serious and pervasive public health problem and appear to be associated with different factors than actual victimization. Our analysis of a population-based telephone survey of youths aged 10-18 years in five economically distressed cities and their suburbs reveals that a substantial minority of youths feel unsafe on any given day, and that an even greater number feel unsafe in school. While some traditional predictors of victimization (such as low socioeconomic status) were associated with feeling unsafe, perceived school disorder was the major factor associated with such feelings. Disorderliness may thus be the school's version of "broken windows," which serve to signal to students a lack of consistent adult concern and oversight that can leave them feeling unsafe. We suggest that fixing the broken windows of school disorderliness may have a significant, positive impact on adolescents' feelings of safety.
- Mikropoulos TA, Strouboulis V. Factors that influence presence in educational virtual environments. *Cyberpsychol Behav* 2004; 7(5):582-91.  
Abstract: The present article is a part of a project for the measurement of presence in educational virtual environments (VEs), since presence is correlated with higher levels of cognitive performance and emotional development, factors that contribute to knowledge construction. The aim of our study was to investigate the sense of presence of 12-year-old pupils within an educational VE representing an ancient Greek house through a sense of embodiment and the ability to

handle task performance, while using various peripheral devices. This is the first report on presence measurement with children, based on the indication that children and adults may apply very unrelated criteria. Our results showed statistically significant differences on the level of tiredness and ease of use in using six different input devices. The combination of the keyboard and mouse and the keyboard on its own were the least tedious and easiest input devices, giving a sense of presence as stated by the pupils. Environmental richness and the high level of interactivity within the VE resulted in a high degree of presence for almost all the pupils. The majority of them felt a sense of presence whilst driving the avatar, indicating that presence is significantly correlated with pupils' degree of association with their virtual bodies. All the pupils felt a sense of presence when wearing the head-mounted display. Our findings are in line with those of other researchers and show evidence of personal, social and environmental presence.

Milazzo AS Jr, Herlong JR, Li JS, Sanders SP, Barrington M, Bengur AR. Real-time transmission of pediatric echocardiograms using a single ISDN line. *Comput Biol Med* 2002; 32(5):379-88. Abstract: We tested the adequacy of a videoconferencing system using a single integrated systems digital network (ISDN) line (128 kilobits per second) for the remote diagnosis of children with suspected congenital heart disease (CHD). Real-time echocardiogram interpretation was compared to subsequent videotape review in 401 studies with concordance in 383 (95.5%) studies. A new diagnosis of CHD was made in 98 studies. Immediate patient transfer was arranged based upon a real-time diagnosis in five studies. In 300 studies, a normal diagnosis obviated further evaluation. A single ISDN line is adequate for transmission of pediatric echocardiograms and it allows for remote management of patients with CHD.

Mildred J. Claimsmakers in the child sexual abuse "wars": who are they and what do they want? *Soc Work* 2003; 48(4):492-503.

Abstract: The research findings described in this article are based on in-depth interviews with 40 people who helped bring concerns about child sexual abuse to audiences in the Western world. The results of this study suggest that significant differences of opinion and perspective exist both within and between the two widely recognized camps of opinion that have developed around this issue. From respondents' descriptions of their own and others' viewpoints, a continuum model of eight positions on issues related to child sexual abuse was developed and is described in this article. Using a social constructionist framework, the author suggests that debates about child sexual abuse, although framed primarily as empirical issues, may reflect moral and political, as well as scientific, disagreements. Debates about issues related to child

sexual abuse take place in larger social and political contexts that include concerns about the family, gender relations, sexuality and sexual behavior, the "science wars," and the role of government. Conflicting claims about practice issues related to child sexual abuse require that social work practitioners be taught to critically examine how the moral and political beliefs of researchers might influence the kinds of questions they ask and how they interpret and frame their research findings.

Milgrom P, Garcia RI, Ismail A, Katz RV, Weintraub JA. Improving America's access to care: The National Institute of Dental and Craniofacial Research addresses oral health disparities. *J Am Dent Assoc* 2004; 135(10):1389-96.

Abstract: BACKGROUND AND OVERVIEW: The National Institute of Dental and Craniofacial Research, or NIDCR, in 2001 sponsored the establishment of Centers for Research to Reduce Oral Health Disparities. The centers are based at Boston University; New York University; the University of Michigan; the University of Washington; and the University of California, San Francisco. Reflecting the importance of research to reduce disparities, the centers, along with related grants, represent one of the largest financial commitments ever made by the NIDCR. The centers are sponsored in part by the National Center on Minority Health and Health Disparities, or NCMHHD. Each of the five centers has forged partnerships that include ties with dental societies, state and local health agencies, community and migrant health centers, American Indian tribal nations and institutions that serve other diverse patient populations. CONCLUSIONS AND CLINICAL IMPLICATIONS: This network is attempting to address the needs of communities with poor oral health. A major part of the effort of these new centers is to build community networks and establish long-term relationships. Center investigators also recognize that solutions to these vexing problems must be built on an understanding of the social, economic, racial, educational, political and behavioral factors that affect most health care issues.

Miller BD. Female-selective abortion in Asia: patterns, policies, and debates. *Am Anthropol* 2001; 103(4):1083-95.

Notes: GENERAL NOTE: KIE: Miller, Barbara D  
GENERAL NOTE: KIE: 80 refs.  
GENERAL NOTE: KIE: KIE Bib: abortion/foreign countries; sex determination  
Abstract: Since the early 1980s, the use of sex-selective abortion increased in many Asian contexts. Estimates indicate that several million female fetuses were aborted in the last two decades of the twentieth century. This article takes a currently unusual approach for a cultural anthropologist in pursuing cross-national comparisons of trends in sex-selective abortion. The risks involved in such an approach are taken in the hope that it will yield insights not gained through

localized analysis. After reviewing the available evidence on female-selective abortion, I discuss features of Asian culture that support strong son preference. Next I review the related issues of increased technological availability for prenatal sex selection and national policies about sex selection. Last, I consider several positions on female-selective abortion and how cultural anthropology may contribute to understanding the global context and consequences of prenatal gender discrimination.

Miller-Johnson S, Coie JD, Maumary-Gremaud A, Bierman K. Peer rejection and aggression and early starter models of conduct disorder. *J Abnorm Child Psychol* 2002; 30(3):217-30.

Notes: CORPORATE NAME: Conduct Problems Prevention Research Group  
Abstract: Peer rejection and aggression in the early school years were examined for their relevance to early starting conduct problems. The sample of 657 boys and girls from 4 geographical locations was followed from 1st through 4th grades. Peer rejection in 1st grade added incrementally to the prediction of early starting conduct problems in 3rd and 4th grades, over and above the effects of aggression. Peer rejection and aggression in 1st grade were also associated with the impulsive and emotionally reactive behaviors found in older samples. Being rejected by peers subsequent to 1st grade marginally added to the prediction of early starting conduct problems in 3rd and 4th grades, controlling for 1st grade ADHD symptoms and aggression. Furthermore, peer rejection partially mediated the predictive relation between early ADHD symptoms and subsequent conduct problems. These results support the hypothesis that the experience of peer rejection in the early school years adds to the risk for early starting conduct problems.

Miller L, France D, Clemetson L *et al.* Sins of the fathers. *Newsweek* 2002; 139(9):42-9, 51-2.

Miller L, Schweingruber H, Oliver R, Mayes J, Smith D. Teaching neuroscience through Web adventures: adolescents reconstruct the history and science of opioids. *Neuroscientist* 2002; 8(1):16-21.  
Abstract: New technological and cultural developments surrounding adolescents' use of the World Wide Web offer an opportunity for turning aspects of the Internet gaming phenomenon to the advantage of neuroscience education. Specifically, an experimental project to transmit aspects of problem-based learning and the National Science Standards through an interactive Web adventure is reported here. The Reconstructors is an episodic Web-based adventure series entitled Medicinal Mysteries from History. It is funded by the National Institute on Drug Abuse, and the first series focuses on opioids. It was created with the input of middle school students and teachers. Through the use of multimedia technologies, middle school students

enter a futuristic world in which they become "reconstructors," members of an elite scientific unit charged with recovering lost medical knowledge about analgesic drugs. Two of the four episodes have been evaluated through a comprehensive review process involving middle school students, teachers, neuroscience researchers, and clinicians. Analysis of the pretest and posttest scores demonstrated significant knowledge gain that validly can be attributed to use of the game. These data provide evidence that science content can be transmitted through innovative online techniques without sacrificing compelling content or effective pedagogical strategies.

Miller-Loncar C, Lester BM, Seifer R *et al.* Predictors of motor development in children prenatally exposed to cocaine. *Neurotoxicol Teratol* 2005; 27(2):213-20.  
Abstract: The current study examined the pattern of motor development across the first 18 months of life in infants with in utero exposure to cocaine to determine how prenatal drug effects and level of exposure relates to motor development. Motor development was examined at 1, 4, 12, and 18 months of age (corrected for prematurity). Infants were divided into cocaine exposed (n=392) and comparison (n=776) groups. Exposure status was determined by meconium assay and maternal self-report with alcohol, marijuana, tobacco, and opiates present in both groups. Motor skills were assessed at 1 month using the NICU Network Neurobehavioral Scale (NNS), at 4 months using the posture and fine motor assessment of infants (PFMAI), at 12 months using the Bayley Scales of Infant Development-Second Edition (BSID-II), and at 18 months using the Peabody Developmental Motor Scales (PDMS). Examiners masked to exposure status performed all assessments. Motor scores were converted to standard (z) scores, and hierarchical linear modeling (HLM) was used to examine the change in motor skills from 1 to 18 months of age. Infants with exposure to cocaine showed low motor skills at their initial status of 1 month but displayed significant increases over time. Both higher and lower levels of tobacco use related to poorer motor performance on average. Heavy cocaine use related to poorer motor performance as compared to no use, but there were no effects of level of cocaine use on change in motor skills.

Miller VA, Drotar D, Burant C, Kodish E. Clinician-parent communication during informed consent for pediatric leukemia trials. *J Pediatr Psychol* 2005; 30(3):219-29.  
Abstract: OBJECTIVE: To address the need to

describe informed consent in pediatric settings and to identify barriers to parent understanding, this study assessed how aspects of clinician-parent communication during the informed consent conference (ICC) relate to parent understanding of informed consent and parent perception of the impact of the ICC on their anxiety and control. **METHODS:** Parents of 127 children with newly diagnosed leukemia who were eligible for clinical trials were the participants. The study used comprehensive methods including both observational and self-report assessment methods. **RESULTS:** Structural equation modeling demonstrated that parent race and socioeconomic status (SES) were powerful predictors of clinician-parent communication, parent anxiety and control as a result of the ICC, and parent understanding. Clinician information giving and partnership building predicted parent participation during the ICC. **CONCLUSIONS:** These findings may be used to design interventions that increase the effectiveness of the ICC by identifying specific elements of the conference that influence parent affect and understanding.

Mimasaka S, Hashiyada M, Nata M, Funayama M. Correlation between serum IL-6 levels and death: usefulness in diagnosis of "traumatic shock"? *Tohoku J Exp Med* 2001; 193(4):319-24. Abstract: Interleukin-6 (IL-6) has been considered as an important mediator of inflammation. Clinically it is a well-known marker of the severity of injury following major trauma. In this study, the levels of IL-6 in body serum were applied to a traumatic death index. Of ninety victims 55 were men and 35 women, with a mean age of 53.4+/- 19 (S.D.) years. The cases were classified as traumatic deaths (38 cases), non-traumatic deaths other than natural causes of deaths (36 cases), and deaths due to natural causes (16 cases). All samples were collected within 2 days after death. The mean values of IL-6 levels of the traumatic, non-traumatic and disease groups were 8608.97, 2205.65, and 3266.64 pg/ml, respectively. Some cases in non-traumatic and disease cases were beyond 10 000 pg/ml, however, the mean value of the traumatic group was statistically higher than that of the other two groups. Even though several cases had high levels of IL-6 in spite of instantaneous death, the results showed that IL-6 levels are helpful in the diagnosis of traumatic shock.

Mimran S, Rotem R. Ocular trauma under the shadow of terror. *Insight* 2005; 30(3):10-2. Abstract: **OBJECTIVES:** To determine the prevalence and severity of penetrating eye trauma (PET) in victims of terror attacks in Jerusalem and to determine their specific in-hospital needs; and to evaluate the role of the ophthalmic nurse in helping to treat these patients in wards other than the ophthalmology ward and to determine how the ophthalmic nurse can coordinate care of the patients with other hospital personnel. **BACKGROUND:** PET is a common cause of significant visual loss. Early treatment is mandatory if

maximum vision is to be restored. From January 2000 through February 2003, 468 victims of terror were examined in one of two major hospitals in Jerusalem that treat ocular injuries; 40 (8.5%) of these patients suffered from PET. **METHODS:** We conducted in our hospital a retrospective chart review of 109 consecutive patients with PET from January 2000 to February 2003; 40 (36.7%) cases were caused by terrorism. Data were collected on demographic characteristics; type, cause and extent of injury; and visual acuity (VA) on admission and at discharge. The terror victims were hospitalized in intensive care, surgical, and ophthalmology wards. **RESULTS:** Of the patients admitted after terrorist attacks, 64% were male. Arab patients comprised 20% of those admitted. Ninety-five percent of the terror victims with PET required surgery (20% for enucleation, 30% for retinal detachment, and the remaining 45% for other causes). Eighty-two percent of these victims presented with a visual acuity > or = 20/200 in the injured eye (versus 63% in patients admitted with ocular trauma from other causes), and 44% remained blind at discharge (versus 28% from other causes). **CONCLUSIONS:** Terror victims have more severe ocular injuries than do other patients with PET. Ophthalmic nurses must make a special effort to attend to these patients in wards other than the ophthalmology wards and to coordinate their in-hospital care and follow-up treatments with hospital personnel in intensive care and surgical wards.

Miner MH, Munns R. Isolation and normlessness: attitudinal comparisons of adolescent sex offenders, juvenile offenders, and nondelinquents. *Int J Offender Ther Comp Criminol* 2005; 49(5):491-504. Abstract: The authors explored attitudinal differences among adolescent male sex offenders, juvenile delinquents, and nondelinquent youth based on three variables drawn from integrated delinquency theory: conventional attitudes, normlessness, and social isolation. Consistent with previous juvenile delinquency studies, the results indicate no differences among the three groups on conventional attitudes. With respect to normlessness, both the sex offenders and juvenile delinquent groups demonstrated more school normlessness than did nondelinquent youths, and adolescent sex offenders showed greater peer normlessness than did either nondelinquent youths or juvenile delinquents. Examination of perceived social isolation among the three groups indicates that sex offenders consistently perceived themselves as more isolated than other youths with their families, in their school, and among their peers. These results suggest that interpersonal factors, in addition to a lack of social controls and normlessness, are associated with sexually inappropriate behavior.

Minkovitz CS, Hughart N, Strobino D *et al.* A practice-based intervention to enhance quality of care in the first 3 years of life: the Healthy Steps for Young Children Program. *JAMA* 2003; 290(23):3081-91. Abstract: CONTEXT: There is growing concern regarding the quality of health care available in the United States for young children, and specific limitations have been noted in developmental and behavioral services provided for children in the first 3 years of life. OBJECTIVE: To determine the impact of the Healthy Steps for Young Children Program on quality of early childhood health care and parenting practices. DESIGN, SETTING, AND PARTICIPANTS: Prospective controlled clinical trial enrolling participants between September 1996 and November 1998 at 6 randomization and 9 quasi-experimental sites across the United States. Participants were 5565 children enrolled at birth and followed up through age 3 years. INTERVENTION: Incorporation of developmental specialists and enhanced developmental services into pediatric care in participants' first 3 years of life. MAIN OUTCOME MEASURES: Quality of care was operationalized across 4 domains: effectiveness (eg, families received > or =4 Healthy Steps-related services or discussed >6 anticipatory guidance topics), patient-centeredness (eg, families were satisfied with care provided), timeliness (eg, children received timely well-child visits and vaccinations), and efficiency (eg, families remained at the practice for > or =20 months). Parenting outcomes included response to child misbehavior (eg, use of severe discipline) and practices to promote child development and safety (eg, mothers at risk for depression discussed their sadness with someone at the practice). RESULTS: Of the 5565 enrolled families, 3737 (67.2%) responded to an interview at 30 to 33 months (usual care, 1716 families; Healthy Steps, 2021 families). Families who participated in the Healthy Steps Program had greater odds of receiving 4 or more Healthy Steps-related services (for randomization and quasi-experimental sites, respectively: odds ratio [OR], 16.90 [95% confidence interval [CI], 12.78 to 22.34] and OR, 23.05 [95% CI, 17.38 to 30.58]), of discussing more than 6 anticipatory guidance topics (OR, 8.56 [95% CI, 6.47 to 11.32] and OR, 12.31 [95% CI, 9.35 to 16.19]), of being highly satisfied with care provided (eg, someone in the practice went out of the way for them) (OR, 2.06 [95% CI, 1.64 to 2.58] and OR, 2.11 [95% CI, 1.72 to 2.59]), of receiving timely well-child visits and vaccinations (eg, age-appropriate 1-month visit) (OR, 1.98 [95% CI, 1.08 to 3.62] and OR, 2.11 [95% CI, 1.16 to 3.85]), and of remaining at the practice for 20 months or longer (OR, 2.02 [95% CI, 1.61 to 2.55] and OR, 1.75 [95% CI, 1.43 to 2.15]). They also had reduced odds of using severe discipline (eg, slapping in face or spanking with object) (OR, 0.82 [95% CI, 0.54 to 1.26] and OR, 0.67 [95% CI, 0.46 to 0.97]). Among mothers considered at risk for depression, those who participated in the Healthy Steps Program had greater odds of discussing their sadness

with someone at the practice (OR, 0.95 [95% CI, 0.56 to 1.63] and OR, 2.82 [95% CI, 1.57 to 5.08]). CONCLUSION: Universal, practice-based interventions can enhance quality of care for families of young children and can improve selected parenting practices.

Minns RA, Busuttill A. Patterns of presentation of the shaken baby syndrome: four types of inflicted brain injury predominate. *BMJ* 2004; 328(7442):766.

Mintz Y, Shapira SC, Pikarsky AJ *et al.* The experience of one institution dealing with terror: the El Aqsa Intifada riots. *Isr Med Assoc J* 2002; 4(7):554-6. Abstract: BACKGROUND: During a period of 13 months--1 October 2000 to 31 October 2001--586 terror assault casualties were treated in the trauma unit and emergency department of Hadassah University Hospital (Ein Kerem campus); 27% (n = 158) were hospitalized and the rest were discharged within 24 hours. OBJECTIVES: To analyze the special requirements of a large number of victims who received treatment during a short period. METHODS: Data were attained from the main admitting office and the trauma registry records. Factors analyzed included age, gender, mechanism of injury, anatomic site of injury, Injury Severity Score, and length of stay. RESULTS: Males comprised 81% of the hospitalized patients. The majority of the injuries (70%) were due to gunshot wounds and 31% of the hospitalized patients were severely injured (ISS > or = 16). Twelve patients died, yielding a mortality rate of 7.5%. CONCLUSION: The nature of the injuries was more complex and severe than trauma of other etiologies, as noted by the mean length of stay (10.2 vs. 7.2 days), mean intensive care unit stay (2.8 vs. 0.9 days), and mean operations per patient (0.7 vs. 0.5). The mean insurance cost for each hospitalized terror casualty was also higher than for other trauma etiologies (US\$ 3,200 vs. 2,500).

Mirsal H, Kalyoncu A, Pektas O, Tan D, Beyazyurek M. Childhood trauma in alcoholics. *Alcohol Alcohol* 2004; 39(2):126-9.

Abstract: AIMS: Many studies have been conducted to evaluate the relationship between childhood trauma and alcoholism. In this study 80 alcoholics were chosen according to their hospitalization order. The control group consisted of 60 subjects, with no history of alcohol use, matched with the patient group in age and sex. METHODS: A sociodemographic and clinical data form, a questionnaire focusing on traumatic life experiences in childhood and The Childhood Trauma Questionnaire, Hamilton Depression Rating Scale, and Hamilton Anxiety Rating Scale were applied to both groups. RESULTS: Significant differences were found between the two groups on traumatic life experiences in childhood. Results suggested that childhood trauma positively correlates with anxiety and affective

- symptoms among alcoholics. **CONCLUSIONS:** Further studies are needed concerning this issue.

- Moe MC, Westerlund U, Varghese M, Berg-Johnsen J, Svensson M, Langmoen IA. Development of neuronal networks from single stem cells harvested from the adult human brain. *Neurosurgery* 2005; 56(6):1182-8; discussion 1188-90.  
Abstract: **OBJECTIVE:** It was long held as an axiom that new neurons are not produced in the adult human brain. More recent studies, however, have identified multipotent cells whose progeny express glial or neuronal markers. This discovery may lead to new therapeutic strategies against central nervous system disorders by transplanting stem cells that have been propagated in vitro. Still, it is not known whether stem cells from the adult human brain retain the potential to mature into neurons that integrate and communicate in a network. **METHODS:** We cultured cells from the ventricular wall of the adult human brain as monoclonal neurospheres. After two passages, the neurospheres were dissociated and the cells were allowed to differentiate. After 4 weeks of maturation, the cells were studied by immunocytochemistry, confocal microscopy, and whole-cell patch-clamp. **RESULTS:** We show that monoclonal stem cells harvested from the ventricular wall of the adult human brain develop into mature neurons with functional glutamate receptors and glutamatergic nerve terminals. By patching pairs of cells simultaneously, we also present direct evidence for synaptic communication between neurons developed from the same monoclonal cell. **CONCLUSION:** Neural stem cells harvested from the adult human brain retain the potential to mature into fully differentiated neurons that integrate and communicate by synapses. This opens a possible future scenario of autotransplantation, in which stem cells are harvested from small biopsies of the ventricular wall and propagated in vitro before transplantation.
- Moen C, Ohlund LS. Negative memories of childhood and current drug use. *Nord J Psychiatry* 2003; 57(4):303-8.  
Abstract: Data on drug abuse and memories of the childhood were collected through a self-report questionnaire from a group of current drug users and a group of non-using controls. Both samples were unidentified as groups by the society and were identified by the researchers through snowball sampling. Earlier results of an unstable childhood and a poor social situation from studies that used other sampling methods were replicated. The drug users had an earlier nicotine and alcohol debut, and perceived themselves as unloved, physically abused children that were afraid of their parents during childhood. In addition, depression, suicide attempts and convictions were more common among the drug users.
- Moghtaderi A, Rahimi-Movaghar V, Safdari M. Spontaneous brain rupture: a complication of untreated hydrocephalus. *Clin Neurol Neurosurg* 2005; 108(1):48-51.  
Abstract: A case of infantile hydrocephalus with secondary spontaneous brain rupture is reported. As far as the authors' knowledge, this is the first case of spontaneous brain and ventricular rupture secondary to high-pressure hydrocephalus. It is a case of infantile hydrocephalus occurring due to the expansibility of an infantile skull, which is normally not seen these days, and is a fatal sequela of untreated hydrocephalus. This rare complication occurs with the rupture of thinnest part of the ependymal layer of the ventricle, cerebral tissue, meningeal membranes, bone and scalp.
- Mohan P. Inequities in coverage of preventive child health interventions: the rural drinking water supply program and the universal immunization program in Rajasthan, India. *Am J Public Health* 2005; 95(2):241-4.  
Abstract: **OBJECTIVES:** I assessed whether the Rural Drinking Water Supply Program (RDWSP) and the Universal Immunization Program (UIP) have achieved equitable coverage in Rajasthan, India, and explored program characteristics that affect equitable coverage of preventive health interventions. **METHODS:** A total of 2460 children presenting at 12 primary health facilities in one district of Rajasthan were enrolled and classified into economic quartiles based on possession of assets. Immunization coverage and prime source of drinking water were compared across quartiles. **RESULTS:** A higher access to piped water by wealthier families ( $P < .001$ ) was compensated by higher access to hand pumps by poorer families ( $P < .001$ ), resulting in equal access to a safe source ( $P = .9$ ). Immunization coverage was inequitable, favoring the wealthier children ( $P < .001$ ). **CONCLUSIONS:** The RDWSP has achieved equitable coverage, while UIP coverage remains highly inequitable. Programs can make coverage more equitable by formulating explicit objectives to ensure physical access to all, promoting the intervention's demand by the poor, and enhancing the support and monitoring of frontline workers who deliver these interventions.
- Mohatt GV, Rasmus SM, Thomas L, Allen J, Hazel K, Hensel C. "Tied together like a woven hat:" Protective pathways to Alaska native sobriety. *Harm Reduct J*

2004; 1(1):10.  
Abstract: BACKGROUND: The People Awakening Project (1R01 AA 11446-03) had two purposes, completed in Phase I and Phase II of the project. The purpose of Phase I was to complete a qualitative study; the research objective was discovery oriented with the specific aim of identification of protective and recovery factors in Alaska Native sobriety. Results were used to develop a heuristic model of protective and recovery factors, and measures based on these factors. The research objective of Phase II was to pilot these measures and provide initial validity data. METHODS: Phase I utilized a life history methodology. People Awakening interviewed a convenience sample of 101 Alaska Natives who had either recovered from alcoholism (n = 58) or never had a drinking problem (n = 43). This later group included both lifetime abstainers (LAs) and non-problem drinkers (NPs). Life histories were transcribed and analyzed using grounded theory and consensual data analytic procedures within a participatory action research framework. Analyses were utilized to generate heuristic models of protection and recovery from alcohol abuse among Alaska Natives. RESULTS: Analyses generated a heuristic model of protective factors from alcohol abuse. The resulting multilevel and multi-factorial model describes interactive and reciprocal influences of (a) individual, family, and community characteristics; (b) trauma and the individual and contextual response to trauma, (c) experimental substance use and the person's social environment; and (d) reflective processes associated with a turning point, or a life decision regarding sobriety. The importance of cultural factors mediating all these protective processes is emphasized. For NPs, the resilience process drew from personal stores of self-confidence, self-efficacy, and self-mastery that derived from ability to successfully maneuver within stressful or potentially traumatizing environments. In contrast, for many LAs, efficacy was instead described in more socially embedded terms better understood as communal mastery. One style of mastery is more associated with individualistic orientations, the other with more collectivistic. Future research is needed regarding the generalizeability of this group difference. CONCLUSIONS: Results suggest that preventative interventions should focus on intervening simultaneously at the community, family, and individual levels to build resilience and protective factors at each level. Of particular importance is the building of reflexivity along with other cognitive processes that allow the individual to think through problems and to reach a life decision to not abuse alcohol.

Mohr WK, Anderson JA. Reconsidering punitive and harsh discipline. *J Sch Nurs* 2002; 18(6):346-52.  
Abstract: Corporal punishment and other harsh interventions continue to be widespread despite the fact that the leading theories or models of behavioral management do not support their effectiveness. There

is overwhelming evidence that harsh interventions are damaging to children, both emotionally and physically. The effects of such trauma may be compounded when a child has preexisting learning difficulties. When schools respond to these challenges using harsh methods, children can be further traumatized. The authors review principles of childhood neurodevelopment, describe a model to understand children in context, and discuss how exposure to certain noxious sensory experiences can affect children's responses to threat or perceived threat. They also describe implications for school nurses.

Molczan KA. Triaging pediatric orthopedic injuries. *J Emerg Nurs* 2001; 27(3):297-300.

Molinari E, Selvini M, Lenzini F. Sexual abuse and eating disorders: clinical cases. *Eat Weight Disord* 2003; 8(4):253-62.

Abstract: The aim of this analysis of five clinical cases is to show how an experience of sexual abuse can contribute towards increasing individual vulnerability and become one of several factors that come together to aggravate and complicate the symptoms characterising eating disorders. It is also intended to enhance the importance of a "multifactorial" model for approaching this kind of psychopathology.

Mollen CJ, Fein JA, Localio AR, Durbin DR. Characterization of interpersonal violence events involving young adolescent girls vs events involving young adolescent boys. *Arch Pediatr Adolesc Med* 2004; 158(6):545-50.

Abstract: BACKGROUND: Multiple studies have demonstrated that girls are engaging in interpersonal violence. However, little is known about the potentially unique aspects of violent events involving girls. OBJECTIVES: To describe characteristics of interpersonal violence events in preadolescents and young adolescents and to determine if events involving any girl are different than those involving only boys. DESIGN: A cross-sectional survey of 8- to 14-year-old patients who were being evaluated at an urban children's hospital emergency department for injuries caused by interpersonal violence was conducted between September 2000 and August 2001. The survey asked the patient to describe details about event circumstances, opponents, weapon use, and injury severity. RESULTS: We enrolled 190 patients into the study; 58 (31%) were girls. Seventy-four events (39%) had a girl involved, 156 (82%) occurred on a weekday, 127 (67%) were classified as fights, 140 (74%) were with a known opponent, and 93 (49%) occurred at school. Events involving girls were more likely than events involving all boys to occur at home (relative risk

[RR], 1.6; 95% confidence interval [CI], 1.0-2.5). Both boys and girls reported "being disrespected" and "teasing" as popular reasons for a fight. Events involving girls were more commonly related to a "recurrence of a previous fight" (RR, 6.4; 95% CI, 1.9-21.5), were more likely to end because of adult intervention (RR, 1.7; 95% CI, 1.1-2.6), and have a family member try to physically break up the fight (RR, 3.7; 95% CI, 1.5-9.1). CONCLUSION: Violent events involving preadolescent and early adolescent girls are more likely to be in response to a previous event and to involve the home environment and family member intervention. Health care professionals should screen violently injured girls for safety concerns and retaliation plans and consider engaging the family in efforts to prevent future events.

Molnar BE, Roberts AL, Browne A, Gardener H, Buka SL. What girls need: recommendations for preventing violence among urban girls in the US. *Soc Sci Med* 2005; 60(10):2191-204.  
Abstract: The last decade saw increases in arrests of girls for violent behavior and a corresponding concern that girls' involvement in violence was increasing in the USA. However, there are few empirical studies of the dynamics of violence by girls, leaving providers of violence prevention programs and policy-makers without evidence on which to base gender-appropriate prevention strategies. To address this gap, qualitative interviews were conducted with a diverse sample of 61 urban girls aged 11-17. Findings were compared with quantitative interviews from the prospective cohort of 961 girls from whom these respondents were drawn, from the Project on Human Development in Chicago Neighborhoods. Mixed-method techniques were employed. Qualitative data were analyzed for girls' recommendations for preventing involvement in violence. Data from the larger cohort were used to test these recommendations quantitatively. Due to study design, in the qualitative sample, 36 girls (64%) were involved in recent violence, most often with or against other girls. Pro-social behavior was common among both violent and nonviolent girls. In the overall cohort sample, 24.9% of girls reported violent perpetration and 97% reported pro-social activities. Eight themes regarding staying safe and preventing violence emerged from the qualitative interviews: girls stayed safe by staying home, avoiding dangerous people, staying busy with after-school activities, remaining calm when confronted, using escorts, and fighting back if attacked. Girls' protective influences included: empathic parental involvement, positive relationships with peers and older youth, and involvement in safe and constructive activities. These findings emphasize that safety in community, school, and family settings is critical for girls in avoiding violence and other risky behaviors. Violence prevention programs should focus on enhancing girls' relationships with mothers, older girls, and friends their age.

Monagle P, Robb B, Driscoll S, Bowes G. Organ retention following paediatric and perinatal autopsy: where to from here? *J Paediatr Child Health* 2002; 38(4):405-8.

Mondaini N, Ponchietti R, Gontero P *et al.* Penile length is normal in most men seeking penile lengthening procedures. *Int J Impot Res* 2002; 14(4):283-6.  
Abstract: Concerns over penile size and a desire for a longer penis are common in the male population. The number of male patients seeking an andrological consultation for the problem of 'short penis' is increasing. We looked at the numbers of patients presenting to a University andrology clinic over a 2-y period and correlated their perceived penis size with the accepted norms. Sixty-seven patients were evaluated with a median age of 27 (range 16-55) complaining of 'short penis' and requesting surgical correction. Clinical history, including the IIEF-5 questionnaire and an accurate physical examination were obtained. Data concerning measures of penile length and circumference were recorded in both the flaccid and fully stretched states and compared to the normal reference range as previously described in the nomogram we recently published (*Eur Urol* 2001; 39: 183-186.). All patients were also asked to estimate the length of a normal sized penis. Forty-four (65.7%) complained of a short penis only while flaccid, 22 patients (32.8%) while both flaccid and erect, and only one patient (1.5%) was worried only by the erect length of the penis. Fifteen (22.4%) also complained about their penile circumference. Fifty-seven (85%) patients thought a 'normal' penile length should range from 10 to 17 cm (median value of 12 cm). Ten patients (15%) were not able to estimate 'normal' penile size. No patient was found to have a penile length under the 2.5 percentile according to our nomogram. Forty-two (62.7%) subjects recalled the problem starting in childhood, when they felt that their penis was smaller than their friends'. In 25 patients (37.3%) the problem started in the teenage years after seeing erotic images. Our data show that most men who seek penile lengthening surgery overestimate 'normal' penile length. In our series, none of the patients could be classified as having a severely short penis according to our nomogram and none had any anatomical penile abnormality. Most found the use of a nomogram to show them how they compared with other men helpful. We suggest that documentation of such a demonstration should be made for any man seeking an opinion on penile lengthening surgery.

Monteiro Caran EM, Dias CG, Seber A, Petrilli AS. Clinical aspects and treatment of pain in children and adolescents with cancer. *Pediatr Blood Cancer* 2005; 45(7):925-32.

Abstract: BACKGROUND: The aim of this study was to characterize the clinical aspects and the treatment of mild to severe pain in Brazilian children and adolescents with cancer. We evaluated the importance of classifying patients according to the phase of cancer treatment (diagnosis, treatment, recurrence, and end-of-life palliative care) and the opioid-related side effects. METHODS: An institutional prospective study of 184 episodes of pain in children and adolescents with cancer was conducted. Pain was classified according to its cause, physiopathology and intensity. Treatment was based on the WHO guidelines for cancer pain relief. RESULTS: Pain scales were completed by 77% of the patients. Numerical scales were used by 49% of them. Morphine was given in 111 episodes for 2,758 patient days. Morphine doses had to be escalated when it was given to patients during end-of-life palliative care. Opioids were well tolerated with no severe side effects. Psychological dependence on morphine was found in 2% (2/111) of the cases. Pain control was satisfactory in 97% of the episodes. CONCLUSIONS: The WHO guidelines for cancer pain relief were effective in controlling pain in children and adolescents with cancer. Despite their low socioeconomic level, patients were able to quantify their pain using rating scales.

Montgomery E. Tortured families: a Coordinated Management of Meaning analysis. *Fam Process* 2004; 43(3):349-71.

Abstract: Torture is known to affect both the individual and the family. The aim of the present study was to reach a better understanding of the significance of communication and information about parental exposure to violence in torture-surviving families. The theoretical background is Social Constructionism and Coordinated Management of Meaning (CMM). In-depth interviews were carried out with 14 members of 3 Middle Eastern refugee families living in Denmark in which the father had been exposed to torture. The 3 families experienced their life stories and situations as refugees in very different ways, ranging from meaninglessness, discontinuance, and alienation to a sense of community, solidarity, and openness. Communications about past events were related to such meaning-providing contexts. The way in which parents talk with their children about torture and organized

violence can be understood in terms of "stories told" and "stories lived." When stories told (e.g., the experience of torture and organized violence) are in contradiction to stories lived, a situation of ambiguity and uncertainty is created. The meaning-providing contexts for making sense of the family history of violence and exile can be more or less coherent or contradictory, and might result in a strengthened relationship or confusion, powerlessness, and action paralysis. Clinicians can help traumatized families deal with their past histories of violence by paying attention to such ambiguities and contradictions.

Montgomery E, Foldspang A. Seeking asylum in Denmark: refugee children's mental health and exposure to violence. *Eur J Public Health* 2005; 15(3):233-7. Abstract: AIMS: The aim of this study was to compare profiles of present mental health and previous exposure to violence among refugee children from the Middle East, whose asylum seeking families either did or did not obtain permission to stay in Denmark. METHODS: Shortly after arrival in Denmark, the parents of 311 Middle-Eastern children answered a structured interview on their children's exposure to organized violence and their mental health. The families were followed-up as concerns receipt of a residence permit. RESULTS: At arrival in Denmark, the children's patterns of previous exposure to violence and present mental health was generally similar irrespective of the family getting a residence permit, as was the case for 90 families (60.4%) with 190 children (61.1%). In both groups an overwhelming majority, eight to nine out of 10 children, had been exposed to conditions of war and had stayed in a refugee camp, and seven out of 10 had witnessed violence. Half of the children had a tortured parent. Considerably more children of families who did not get a residence permit had lost a parent (30.6% versus 13.7%;  $P < 0.001$ ). In both groups about two-thirds suffered from anxiety and about 30% from sleep problems, and children whose families did not later on get a residence permit more often appeared sad or miserable (43.8% versus 27.9%;  $P < 0.005$ ). CONCLUSIONS: The asylum-granting decision process seems to have divided the children into two groups with only superficial disparity as concerns their previous exposure to violence and their present mental health. There seems to be good reason to systematically integrate evidence on the children of refugee families in the treatment of applications for permission to stay.

Montgomery E, Foldspang A. Traumatic experience and sleep disturbance in refugee children from the Middle East. *Eur J Public Health* 2001; 11(1):18-22. Abstract: BACKGROUND: Sleep disturbance is frequently reported in children after traumatic experiences associated with organised violence. The aim of this study was to identify specific traumatic risk indicators and modifying factors for sleep disturbance among recently arrived refugee children from the Middle East. METHODS: The study group comprises

311, 3-15 year old refugee children from the Middle East. On arrival in Denmark, their parents participated in a structured interview about their children's health and history of exile and eventual exposure to war, organised violence and human rights violation. RESULTS: A family history of violence (grandparent's violent death before the birth of the child or parental exposure to torture) as well as a stressful present family situation (father scolds the child more than previously) were the strongest predictors of prevalent sleep disturbance in the children. Arriving in Denmark with both parents rather than one was a modifying factor, so the effect of traumatic experience on sleep patterns later in childhood was mediated through parental presence and behaviour. CONCLUSION: This study indicates that the family environment is of primary importance for childhood sleep disturbance following traumatic experiences connected with war and other organised violence.

Montigny F, Lacharite C. Perceived parental efficacy: concept analysis. *J Adv Nurs* 2005; 49(4):387-96. Abstract: AIMS: This paper describes a concept analysis carried out to remove some of the ambiguity surrounding the conceptual meaning of perceived parental efficacy and to distinguish it from related concepts such as parental confidence and parental competence. BACKGROUND: Constructing parental efficacy is a crucial step for family members after the birth of their first child. For some authors, perceived parental efficacy is a motor for adequate parental practices. Confusion about the definition and measurement of this concept has hindered both psychology and nursing practice and research. Concept delineation and concept clarification are required in order to further the development of the concept of perceived parental efficacy. METHODS: A literature search using a variety of online databases yielded 113 articles between the years 1980 and 2000. The final sample (n=60) consisted of 30 articles from two disciplines: nursing and psychology. A content analysis of the literature was done using Rodger's evolutionary concept analysis method. FINDINGS: Content analysis of the literature yielded four contributors to perceived parental efficacy: positive enactive mastery experiences, vicarious experiences, verbal persuasion and an appropriate physiological and affective state. Perceived parental efficacy can thus be defined as 'beliefs or judgements a parent holds of their capabilities to organize and execute a set of tasks related to parenting a child'. CONCLUSION: This conceptual analysis has allowed perceived parental efficacy to be distinguished from parental confidence and parental competence. Both nursing and psychology research, practice and education will benefit from a more precise and delineated concept.

Moody-Williams JD, Krug S, O'Connor R, Shook JE, Athey JL, Holleran RS. Practice guidelines and performance measures in emergency medical services for children.

*Ann Emerg Med* 2002; 39(4):404-12. Abstract: Practice guidelines and performance measures are critical elements of an effective quality improvement process for emergency medical services for children (EMSC). Practice guidelines address the clinical management of individual patients, and performance measures assess the quality of care delivered to a population. The public and private sectors have invested considerable resources in developing practice guidelines and performance measures to improve the quality of health care services. As organizations continue development efforts, health care professionals who are actively involved in emergency care must collaborate to develop guidelines that address the unique physiologic, psychologic, and cultural needs of children. The Emergency Medical Services for Children Managed Care Task Force recommended the development of a series of white papers to focus on issues related to practice guidelines and performance measures in EMSC. The Maternal and Child Health Bureau, Health Resources and Services Administration, the National Highway Traffic Safety Administration, and the Robert Wood Johnson Foundation jointly sponsored the project. The paper was developed by a panel selected from a pool of experts in managed care, quality improvement, and emergency medical services. After a review of the literature, the panelists met to discuss critical issues related to practice guidelines and performance measures in EMSC. The panelists developed recommendations that can serve as resources for managed care organizations, health care providers, professional associations, and governmental policy makers. The panel recognized the lack of nationally recognized pediatric emergency care guidelines and performance measures and called for immediate action in these areas.

Mooney JF 3rd, Cramer KE. Lower extremity compartment syndrome in infants associated with child abuse: a report of two cases. *J Orthop Trauma* 2004; 18(5):320-2.

Abstract: Compartment syndrome associated with child abuse is unreported in the literature. We describe two cases secondary to lower extremity fractures resulting from child abuse. The diagnosis and management of compartment syndrome are reviewed. Orthopaedic surgeons involved in the care of pediatric patients must be aware of this potentially devastating complication, and must be prepared for timely management.

Moore C, Dunkelberg E, Chivers L, O'Berg J, Waldinger RJ. The role of shame and guilt in male aggression toward partners. *J Am Psychoanal Assoc* 2004; 52(2):480-1.

Moore KA, Coker K, DuBuisson AB, Swett B, Edwards WH. Implementing potentially better practices for improving family-centered care in neonatal intensive care units: successes and challenges. *Pediatrics* 2003;

Abstract: OBJECTIVE: Multidisciplinary teams from 11 medical center neonatal intensive care units collaborated in a quality improvement project with a focus on family-centered care. METHODS: Through a process of self-analysis, literature review, benchmarking site visits, and expert consultation, 10 potentially better practice (PBP) areas were defined. Improvement activities in 4 of the 10 areas are given as examples of successes and challenges that individual centers encountered. The 4 areas are vision and philosophy, unit culture, family participation in care, and families as advisors. RESULTS: Centers were at different places for all of the PBPs at the beginning and throughout the collaboration. Seven centers developed or revised their vision or philosophy of care statements about family-centered care. Incorporating the vision and philosophy of care into performance appraisals, hiring of new personnel, and changing unit culture to a more family-centered practice were more challenging than developing the statements. Full parent participation in care requires unrestricted access to the neonatal intensive care unit. The shift from considering parents to be "visitors" to being partners in caring for their child was more difficult for centers with restricted visitation policies. All centers developed, expanded, or started plans for establishing family advisory councils. The experience of 2 centers is described. CONCLUSIONS: Family-centered care is more of a journey than a destination. Collaborating centers in this project found themselves at different places in that journey. Through perseverance in implementing the PBPs, all have moved further along the path.

Moore PD, Bay RC, Balcazar H, Coonrod DV, Brady J, Russ R. Use of home visit and developmental clinic services by high risk Mexican-American and white non-Hispanic infants. *Matern Child Health J* 2005; 9(1):35-47.

Abstract: OBJECTIVE: To investigate whether US-born infants of mothers of Mexican descent who were enrolled in Arizona's Newborn Intensive Care Program (NICP) received follow-up services (developmental clinic and community health nurse [(CHN)] home visits) at the rates similar to White non-Hispanic (WNH) infants. Socio-economic and health status characteristics were controlled using stepped regressions in order to assess the impact of each on service use. METHODS: This population-based study used retrospective data from the NICP administrative database that were linked to birth certificates for years 1994-1998. The study population was limited to Arizona-born infants; it included 7442 infants of WNH mothers, 2612 infants of US-born Mexican American (MA) mothers and 2872 infants of Mexico-born mothers. Four service use indicators were used in the analysis. RESULTS: Both Hispanic infant subgroups were less likely to have a CHN visit by 6 months and by 1 year, and to average fewer CHN visits. A smaller percent attended the developmental clinic by age one.

After controlling for language, demographics, health status, socio-economic characteristics, and mothers' prenatal care use, infants of US-born MA mothers had rates of use similar to WNH. However, even after controlling for the study variables, infants of Mexico-born mothers were less likely (OR = .83) to use the developmental clinic. Hispanics continued to lag behind in the use of services compared with WNHs. The disparity is not a function of ethnicity, but appears attributable to demographic and socio-economic characteristics. Infants who had a CHN visit were significantly more likely (OR = 2.51) to use the developmental clinic than those without a nurse visit. Infants whose mothers had inadequate prenatal care were less likely to use these follow-up services even after controlling for study variables. CONCLUSIONS: Infants whose mothers had inadequate prenatal care should be targeted for more intense CHN visits. Infants of mothers born in Mexico may need additional support/assistance in using the developmental clinic.

Morad Y, Avni I, Capra L *et al.* Shaken baby syndrome without intracranial hemorrhage on initial computed tomography. *J AAPOS* 2004; 8(6):521-7.  
Abstract: OBJECTIVE: We sought to describe the unique characteristics of children diagnosed with shaken baby syndrome (SBS) despite the absence of intracranial hemorrhage on cranial computerized tomography (CT) on hospital admission. METHODS: Using an international e-mail-based listserv for professionals with an interest in child abuse, we identified and reviewed the charts of children hospitalized in different medical centers who were diagnosed with SBS although CT disclosed no signs of intracranial bleeding. Children with normal imaging were not included. RESULTS: Eight cases were identified. All children had cerebral edema in CT, which was severe on 7/8 cases (88%). All of these children had extensive retinal hemorrhage. The prognosis was poor; 5/8 infants died (63% mortality), and the rest had permanent neurologic damage. CONCLUSION: The diagnosis of SBS can be established even when CT at presentation does not demonstrate intracranial hemorrhage. We hypothesize that rapidly developing cerebral edema may cause increased intracranial pressure and tamponade that prevents the accumulation of intracranial blood. The

prognosis in these cases is grave.

Morad Y, Kim YM, Mian M, Huyer D, Capra L, Levin AV. Nonophthalmologist accuracy in diagnosing retinal hemorrhages in the shaken baby syndrome. *J Pediatr* 2003; 142(4):431-4.

Abstract: Nonophthalmologists did not attempt to (36%) or were "unable to" (19%) examine the fundus in 72 children with shaken baby syndrome. When the retina was examined, nonophthalmologists were accurate in recognizing the absence or presence of retinal hemorrhage in 87%. However, false-negative examinations occurred in 13%. Ophthalmology consultation should be an integral part of the evaluation of children with suspected abuse.

Moraes LR, Cancio JA, Cairncross S, Huttly S. Impact of drainage and sewerage on diarrhoea in poor urban areas in Salvador, Brazil. *Trans R Soc Trop Med Hyg* 2003; 97(2):153-8.

Abstract: A longitudinal prospective study of the effect of drainage and sewerage systems on diarrhoea in children aged < 5 years was conducted in 9 poor urban areas of the city of Salvador (population 2.44 million) in north-east Brazil in 1989-90. Due to complex political and administrative reasons, 3 areas had benefited from drainage improvements, 3 from both drainage and sewerage improvements, and 3 from neither. An extensive questionnaire was applied to collect information on each child and on the conditions of the household, and mothers recorded diarrhoea episodes in their children aged < 5 years daily for 1 year, using calendars. Fortnightly home visits were made to collect the data. The incidence of diarrhoea in children in neighbourhoods with drainage was less than two-thirds, and in neighbourhoods with drainage and sewerage less than one-third, of the incidence in neighbourhoods with neither. After controlling for potential confounders, the proportion of children with 'frequent diarrhoea' showed the same significant trend across the study groups. Though the groups were not exactly comparable, more than one child was monitored per household, and it was not possible to rotate fieldworkers between study groups, the study provides evidence that community sanitation can have an impact on diarrhoeal disease, even without measures to promote hygiene behaviour.

Morano JP. Sexual Abuse of the Mentally Retarded Patient: Medical and Legal Analysis for the Primary Care Physician. *Prim Care Companion J Clin Psychiatry* 2001; 3(3):126-35.

Abstract: The primary care physician has a vital role in documenting and preventing sexual abuse among the mentally retarded populations in our community. Since the current national trend is to integrate citizens with mental retardation into the community away from institutionalized care, it is essential that all physicians have a basic understanding of the unique medical and

legal ramifications of their clinical diagnoses. As the legal arena is currently revising laws concerning rights of sexual consent among the mentally retarded, it is essential that determinations of mental competency follow national standards in order to delineate clearly any instance of sexual abuse. Clinical documentation of sexual abuse and sexually transmitted disease is an important part of a routine examination since many such individuals are indeed sexually active. Legal codes adjudicating sexual abuse cases of the mentally retarded often offer scant protection and vague terminology. Thus, medical documentation and physician competency rulings form a solid foundation for future work toward legal recourse for the abused.

Moreno L, Sanchez JL, Manas S *et al.* Tools for acquisition, processing and knowledge-based diagnostic of the electroencephalogram and visual evoked potentials. *J Med Syst* 2001; 25(3):177-94.

Abstract: The objective of our research is to develop computer-based tools to automate the clinical evaluation of the electroencephalogram (EEG) and visual evoked potentials (VEP). This paper describes a set of solutions to support all the aspects regarding the standard procedures of the diagnosis in neurophysiology, including: (1) acquisition and real-time processing and compression of EEG and VEP signals, (2) real-time brain mapping of spectral powers, (3) classifier design, (4) automatic detection of morphologies through supervised neural networks. (5) signal analysis through fuzzy modelling, and (6) a knowledge based approach to classifier design.

Moriyama M, Suwa T, Kabuto M, Fukushima T. Participatory assessment of the environment from children's viewpoints: development of a method and its trial. *Tohoku J Exp Med* 2001; 193(2):141-51.

Abstract: To understand the actual viewpoints of children about daily life and the environment, the authors, adopting a participatory strategy, visited 21 classes of Japanese school children, improved in a stepwise process their ways of question-asking, and developed "WIFY"(what is important for you); a set of interactive questions composed of a basic question and three accompanying instructions. In applying WIFY, 59 fourth graders, 22 in Nagasaki, Japan and 37 in Beijing, China, reported their viewpoints in each of classroom settings. In both settings, when children were allowed to communicate with each other by the use of WIFY answering sheet, spontaneous exchanges arose and continued. WIFY itself is supposed to bring

out and enhance mutual collaboration and spontaneous networking. In this instance, WIFY functioned as a communication tool. When answering sheets were collected and obtained responses were analyzed as cases, a rather materialistic view was suggested among Japanese children and a more disciplined view, which put much value on school and home, was suggested among Chinese children. Further studies are needed to confirm the changing environmental views of children from the collaborative research framework.

Mork M. [Medical problems and needs of follow-up in a group of children with mild cerebral palsy]. *Tidsskr Nor Laegeforen* 2001; 121(13):1566-9. Abstract: **BACKGROUND:** There is no specialized health service for routine follow-up for ambulatory children with cerebral palsy in Rogaland county. Our aim was to investigate the kind of medical problems these children had and whether these problems were discovered by the health services. **MATERIAL AND METHODS:** 37 children with cerebral palsy born 1987-1992 were investigated. They were all independent walkers without mental retardation at the time of selection. The majority had spastic hemiplegia or spastic diplegia. Their parents were interviewed and the children underwent a neurological examination. **RESULTS:** Orthopedic problems such as scoliosis, hip abnormalities, tight tendons and muscles, and leg length discrepancy were not discovered by the local health service. The children had a high incidence of epilepsy, visual disorders and minor speech problems. Minor learning difficulties were frequent. **INTERPRETATION:** Children with mild cerebral palsy have specific problems and need the attention of neuropediatricians in order to establish the primary and secondary problems involved.

Morrill AC, Dai J, Dunn S, Sung I, Smith K. Child custody and visitation decisions when the father has perpetrated violence against the mother. *Violence Against Women* 2005; 11(8):1076-107. Abstract: This research evaluated the effectiveness of statutes mandating a presumption against custody to a perpetrator of domestic violence (DV) and judicial education about DV. Across six states, the authors examined 393 custody and/or visitation orders where the father perpetrated DV against the mother and surveyed 60 judges who entered those orders. With the presumption, more orders gave legal and physical custody to the mother and imposed a structured schedule and restrictive conditions on fathers' visits, except where there was also a "friendly parent" provision and a presumption for joint custody. The presumption is effective only as part of a consistent statutory scheme. Although 86% of judges had received DV education, they scored no better in knowledge or attitudes. More of their orders gave mothers sole physical custody, and knowledge was associated with maternal custody, yet fewer structured or restricted fathers' visitation. Quality of DV

education is more important than statutory mandate.

Morrongiello BA, Kiriakou S. Mothers' home-safety practices for preventing six types of childhood injuries: what do they do, and why? *J Pediatr Psychol* 2004; 29(4):285-97.

Abstract: **OBJECTIVE:** To identify determinants of mothers' home-safety practices for preventing six types of common injuries to children (burns, poisoning, drowning, cuts, strangulation/suffocation/choking, and falls). **METHODS:** Home interviews were conducted with mothers of children 19-24 and 25-30 months old about home-safety practices. For each of 30 safety precautions to prevent these six types of injuries, mothers indicated whether or not they engaged in the practice, and explained why. **RESULTS:** Regression analyses revealed both common and unique determinants of mothers' home-safety practices to prevent these six types of home injuries. For burns, cuts, and falls, beliefs that child characteristics and parent characteristics elevated the child's risk of injury were the key determinants of the mother's engaging in precautionary measures. For drowning, poisoning, and suffocation/strangulation/choking, health beliefs also contributed to predict mothers' practices, including beliefs about potential injury severity and extent of effort required to implement precautionary measures. **CONCLUSIONS:** The factors that motivated mothers to engage in precautionary measures at home varied depending on the type of injury. Intervention programs to enhance maternal home-safety practices will need to target different factors depending on the type of injury to be addressed.

Morrow AL, Guerrero ML. From bioactive substances to research on breast-feeding promotion. *Adv Exp Med Biol* 2001; 501:447-55.

Abstract: Despite known health benefits, exclusive breast-feeding for at least 4 months is uncommon in many countries. In Mexico, most mothers initiate breast-feeding but few breast-feed exclusively. **OBJECTIVE:** The objective was to examine the effectiveness of home visits by lay peer counselors to increase exclusive breast-feeding among mothers in a periurban area of Mexico. **METHODS:** An ethnographic assessment conducted in 1994 that identified key maternal beliefs, practices, and needs was used to guide educational strategies. Lay counselors were recruited from the same community and trained by La Leche League. From March 1995 through September 1996, pregnant women were identified by community census and invited to participate. Women were enrolled into a randomized, controlled study of 3 groups: no intervention (control), 3 visits, and 6 visits during pregnancy and early postpartum. Data collection was performed by a social worker apart from the counselors. Exclusive breast-feeding was defined by WHO criteria. **RESULTS:** The study enrolled 130 women; 52 were in the 3-visit group, 44 in the 6-visit group, and 34 in the control

group. Study groups did not differ in the maternal characteristics or initiation of breast-feeding (96%). At 3 months postpartum, exclusive breast-feeding was practiced by only 12% of controls vs. 52% in the 3-visit group and 67% in the 6-visit group ( $P < 0.001$ , log rank test). In the first 3 months, significantly ( $P = 0.037$ ) fewer intervention than control infants had an episode of diarrhea (11% vs. 26%, respectively). Intervention effectiveness was independent of maternal factors or birth hospital. CONCLUSIONS: This unique experimental study demonstrated a dramatic increase in exclusive breast-feeding and a significant reduction in infant illness in an urban community through well-designed maternal support including early intervention and repeated contact.

Morrow OI, Sweat MD, Morrow RH. The matalisi: pathway to early sexual initiation among the youth of Mpigi, Uganda. *AIDS Behav* 2004; 8(4):365-78. Abstract: This paper describes the role and personal characteristics of the "matalisi," a previously unreported phenomenon uncovered during a study of youth sexual behavior in Uganda. The "matalisi," a go-between, played a central role in sexual relationships of most youth in Mpigi, Uganda. The first phase of the study was an ethnographic inquiry of youth (ages 10-16) sexual behavior. During this phase it became evident that matalisis were used in most courtships and initial sexual liaisons. The second phase included a sociometric investigation of youth networks and a mini survey of youth who had been matalisis. Among youth interviewed, 47.3% of males (105/222) and 14.1% of females (42/298) had experienced sexual intercourse. For 88%, participating as someone's matalisi preceded first coitus. By understanding the role of the matalisi, interventions may be developed to improve sex education and more effectively address sexual behaviors that lead to unwanted pregnancies, STIs, and HIV infection.

Morrow V. Using qualitative methods to elicit young people's perspectives on their environments: some ideas for community health initiatives. *Health Educ Res* 2001; 16(3):255-68. Abstract: This paper describes qualitative methods used in a research project for the former Health Education Authority, exploring Putnam's concept of 'social capital' in relation to children and young people's well-being and health. Putnam's conceptualization of social capital consists of the following features: trust, reciprocal support, civic engagement, community identity and social networks, and the premise is that levels of social capital in a community have an important effect on people's well-being. Research was carried out with 102 children aged between 12 and 15 in two relatively deprived parts of a town in southeast England. The paper describes the research setting, methods, consent process and ethical issues that arose. It explores how the methods generated different forms of interconnected data,

giving rise to a number of health/well-being-related themes. The paper concludes that using a range of methods, including visual methods, has helped to explore quality of life issues for children that are usually neglected in studies of young people's health-related behaviours.

Morton JB, Munakata Y. Active versus latent representations: a neural network model of perseveration, dissociation, and decalage. *Dev Psychobiol* 2002; 40(3):255-65. Abstract: Children of different ages often perseverate, repeating previous behaviors when they are no longer appropriate, despite appearing to know what they should be doing. Using neural network models, we explore an account of these phenomena based on a distinction between active memory (subserved by the prefrontal cortex) and latent memory (subserved by posterior cortex). The models demonstrate how (a) perseveration occurs when an active memory of currently relevant knowledge is insufficiently strong to overcome a latent bias established by previous experience, (b) apparent dissociations between children's knowledge and action may reflect differences in the amount of conflict between active and latent memories that children need to resolve in the tasks, and (c) differences in when children master formally similar tasks (decalage) may result from differences in the strength of children's initial biases. The models help to clarify how prefrontal development may lead to advances in flexible thinking.

Morton JB, Munakata Y. What's the difference? Contrasting modular and neural network approaches to understanding developmental variability. *J Dev Behav Pediatr* 2005; 26(2):128-39. Abstract: Understanding why development differs across individuals is an important challenge for developmental theory. This paper evaluates two approaches to developmental variability observed in domains such as language processing and across populations such as typically developing children, children with developmental disorders, and typical adults. Modular accounts attribute developmental variability to delay, damage, or dysfunction in discrete underlying structures. Neural network approaches attribute developmental variability to emergent effects of graded variations in an interactive, developing system. The authors conclude that neural network approaches offer more formal and parsimonious accounts of the nature and sources of developmental variability.

Moskalewicz J, Zulewska-Sak J. [Alcohol drinking in the time of political transition in Poland. Report of the National Health Programme ]. *Przegl Epidemiol* 2003; 57(4):713-23. Abstract: The National Health Programme was adopted in Poland in the mid-1990s. It consists of 18 targets

including target 4 that calls for diminishing alcohol consumption and changing its structure as well as limiting health harms associated with alcohol. The programme is being monitored on bi-annual basis. The monitoring covers a level of alcohol consumption and associated harm including trends in mortality and morbidity as well as in road accidents in 1990-2001 period. During the period in point, particularly in the beginning of the transition alcohol consumption increased at least by one third reaching 10-11 litres of pure ethanol per capita, mostly due to sudden disruption of the alcohol control system and high tide of unrecorded supply. Currently, the consumption is estimated to be 9.5-10.0 litres with 30% share of the unrecorded. During last decade recorded morbidity due to mental disorders associated with alcohol increased by 80% and 60% respectively in out- and in-patient system while mortality rates almost doubled. Male mortality due to liver diseases increased by 50% while that of women remained relatively flat. In last few years, alcohol related mortality tended to decline slightly parallel to consumption trends. Significant improvement has been achieved in prevention of drunken diving. The number of deaths in alcohol related road accidents decreased two fold while a rate of drunken crashes per 1000 vehicles dropped three times.

Moss HB, Lynch KG, Hardie TL. Affiliation with deviant peers among children of substance dependent fathers from pre-adolescence into adolescence: associations with problem behaviors. *Drug Alcohol Depend* 2003; 71(2):117-25.  
Abstract: OBJECTIVE: Affiliation with delinquent peers has been shown to be a major risk factor for the development of antisocial and substance abuse behaviors in adolescence. However, little data are available concerning the developmental trajectories of deviant peer affiliation. METHOD: In this study, we have prospectively examined the density of deviant peers among the social networks of children of drug dependent fathers at age 10, and at 2 and 5 year follow-ups, and compared them with those of controls. Measures of internalizing and externalizing psychopathology were employed as time varying covariates, while socioeconomic status (SES) was used as a time invariant covariate. A pattern mixture analysis of missing data was conducted. RESULTS: Using mixed effects models, we found significant main effects of time, group, externalizing psychopathology, and to lesser extent, SES on the magnitude of affiliation with deviant peers. Greater deviant peer affiliation among the high-risk children was found at each time point. Externalizing psychopathology augmented the magnitude of deviant peer affiliation in both high-risk and comparison children. CONCLUSION: Offspring of drug dependent fathers have heightened affiliation with deviant peers from pre-adolescence through mid-adolescence. This social developmental process may be a component of the

familial risk for substance abuse and antisocial behaviors.

Moss HB, Lynch KG, Hardie TL, Baron DA. Family functioning and peer affiliation in children of fathers with antisocial personality disorder and substance dependence: associations with problem behaviors. *Am J Psychiatry* 2002; 159(4):607-14.  
Abstract: OBJECTIVE: Family functioning and peer influences are theoretically linked to child psychopathology. This study quantified the functional status of families with fathers with substance dependence with or without comorbid antisocial personality disorder and evaluated the peer environments of preadolescent offspring. The authors examined associations between the child's psychopathology, paternal substance dependence/antisocial personality disorder status, and measures of family and peer environments. METHOD: Families with the presence or absence of paternal substance dependence were subdivided into those with and without paternal antisocial personality disorder. Grouped families were contrasted on measures of family functioning, the child's peer affiliation, and the child's problem behaviors. Regression analysis determined the influence of these factors on the child's psychopathology. RESULTS: Families with paternal substance dependence functioned worse than normal comparison families. However, families with paternal substance dependence and antisocial personality disorder (N=34) did not differ markedly from those with substance dependence without antisocial personality disorder (N=84). The children of fathers with both substance dependence and antisocial personality disorder had greater affiliation with deviant peers than those with substance dependence without antisocial personality disorder and comparison families (N=104). CONCLUSIONS: Children of fathers with substance dependence and antisocial personality disorder demonstrated higher externalizing and internalizing psychopathology than those with substance dependence but not antisocial personality disorder and those without either condition. Paternal substance dependence/antisocial personality disorder status and the child's affiliation with deviant peers were most robustly associated with the child's psychopathology. Research is needed to develop interventions that effectively address parental risk and healthy peer relations.

Moura AT, Reichenheim ME. [Are we really detecting violence in families of children visiting our health services? The experience of a public health service in Rio de Janeiro, Brazil]. *Cad Saude Publica* 2005; 21(4):1124-33.  
Abstract: Domestic violence, particularly in childhood, is a growing public health concern. Information on morbidity is mostly underreported due to constraints in case detection. This paper analyzes the frequency of events measured actively by outpatient services as

compared to spontaneous reports. Information on violence was assessed for 245 families from April to June 2001 using the Conflict Tactics Scales: Parent-Child Version (CTS-PC) and the Revised Conflict Tactics Scales (CTS2). Cases referred to the Social Work Department provided the caseload for the active search period (12 months). There was a high prevalence of physical violence in the couple, with serious events occurring in 17.0% of the families. In relation to children, cases of "minor" physical aggression were reported in 46.0% of families and serious cases in 9.9%. The spontaneously identified prevalence was 3.3%. This case study demonstrates the missed opportunities for detection and calls attention to the need to review the approach to domestic violence by health services.

Mouradian WE, Schaad DC, Kim S *et al.* Addressing disparities in children's oral health: a dental-medical partnership to train family practice residents. *J Dent Educ* 2003; 67(8):886-95.

Abstract: Providing oral health care to rural populations in the United States is a major challenge. Lack of community water fluoridation, dental workforce shortages, and geographical barriers all aggravate oral health and access problems in the largely rural Northwest. Children from low-income and minority families and children with special needs are at particular risk. Family-centered disease prevention strategies are needed to reduce oral health disparities in children. Oral health promotion can take place in a primary care practitioner's office, but medical providers often lack relevant training. In this project, dental, medical, and educational faculty at a large academic health center partnered to provide evidence-based, culturally competent pediatric oral health training to family medicine residents in five community-based training programs. The curriculum targets children birth to five years and covers dental development, the caries process, dental emergencies, and oral health in children with special needs. Outcome measures include changes in knowledge, attitudes, and self-efficacy; preliminary results are presented. The program also partnered with local dentists to ensure a referral network for children with identified disease at the family medicine training sites. Pediatric dentistry residents assisted in didactic and hands-on training of family medicine residents. Future topics for oral health training of family physicians are suggested.

Mowbray CT, Lewandowski L, Bybee D, Oyserman D. Children of mothers diagnosed with serious mental illness: patterns and predictors of service use. *Ment Health Serv Res* 2004; 6(3):167-83. Abstract: Children who have a parent diagnosed with a mental illness are at risk of psychiatric and behavioral problems; yet, these children do not necessarily receive needed services. Research has investigated correlates of child mental health service use, but not for these high-risk children. This study is part of an NIMH-

funded, longitudinal investigation and describes child problems, service use, and predictors of service use for 506 children of 252 mothers diagnosed with serious mental illness. Mothers are primarily poor, minority women from urban areas. A multilevel-model approach is used to examine service use for multiple siblings in a family. More than one third of children had received services (from school or mental health agencies) in their lifetimes. Service use was predicted by child demographic characteristics (being male, non-African American, and older), social context variables (more negative life events, less financial satisfaction, and more parenting dissatisfaction), and maternal psychiatric variables (positively by high levels of case management receipt and affective diagnoses, negatively by maternal substance abuse history). In a subsample of "target children," mothers' rating of child behavior problems additionally predicted service use. Implications of results for research and intervention are discussed.

Moya FR, Lally KP. Evidence-based management of infants with congenital diaphragmatic hernia. *Semin Perinatol* 2005; 29(2):112-7.

Abstract: The mortality rate associated with congenital diaphragmatic hernia (CDH) varies widely between centers and remains relatively high despite widespread use of new therapeutic modalities. Many of these have been implemented without properly controlled studies. Over the past 10 to 15 years, only 9 randomized trials enrolling a total of approximately 250 infants with CDH have been published. The limited evidence available suggests that better outcomes are observed by delivering infants with CDH at experienced centers, by delaying surgical repair until hemodynamic and respiratory stability is achieved, and by the judicious utilization of nonaggressive mechanical ventilation and permissive hypercapnea. Other therapeutic modalities, such as high frequency oscillatory ventilation, inhaled nitric oxide, and ECMO, may provide additional advantages for selected infants. There is a dire need to establish networks of centers that manage enough infants with CDH, to conduct appropriately sized randomized trials that can answer some of the critical questions about the management and long-term outcome of these infants.

Mueller M, Wagner CL, Annibale DJ, Hulsey TC, Knapp RG, Almeida JS. Predicting extubation outcome in preterm newborns: a comparison of neural networks with clinical expertise and statistical modeling. *Pediatr Res* 2004; 56(1):11-8.

Abstract: Even though ventilator technology and monitoring of premature infants has improved immensely over the past decades, there are still no standards for weaning and determining optimal extubation time for those infants. Approximately 30% of intubated preterm infants will fail attempted extubation, requiring reintubation and resuming of mechanical ventilation. A machine-learning approach

using artificial neural networks (ANNs) to aid in extubation decision making is hereby proposed. Using expert opinion, 51 variables were identified as being relevant for the decision of whether to extubate an infant who is on mechanical ventilation. The data on 183 premature infants, born between 1999 and 2002, were collected by review of medical charts. The ANN extubation model was compared with alternative statistical modeling using multivariate logistic regression and also with the clinician's own predictive insight using sensitivity analysis and receiver operating characteristic curves. The optimal ANN model used 13 parameters and achieved an area under the receiver operating characteristic curve of 0.87 (out-of-sample validation), comparing favorably with multivariate logistic regression. It also compared well with the clinician's expertise, which raises the possibility of being useful as an automated alert tool. Because an ANN learns directly from previous data obtained in the institution where it is to be used, this makes it particularly amenable for application to evidence-based medicine. Given the variety of practices and equipment being used in different hospitals, this may be particularly relevant in the context of caring for preterm newborns who are on mechanical ventilation.

Mueller M, Wagner CL, Annibale DJ, Hulsey TC, Knapp RG, Almeida JS. Web-based prediction of extubation outcome in premature infants on mechanical ventilation using an artificial neural network. *AMIA Annu Symp Proc* 2003; 945. Abstract: The web-based implementation of a decision-support tool for the prediction of extubation outcome in mechanically ventilated premature infants enables the integration of advanced and computationally intensive modeling approaches with easy-usage, no maintenance requirements and wide availability. Accordingly, the artificial neural network predictive tool developed provides decision-support in determining whether to extubate a premature infant to clinicians in NICUs anywhere with access to the Internet.

Muennig P, Franks P, Jia H, Lubetkin E, Gold MR. The income-associated burden of disease in the United States. *Soc Sci Med* 2005; 61(9):2018-26. Abstract: In this study, we estimate the total burden of disease associated with income in the US. We calculate the relationships between income and life expectancy, health-adjusted life expectancy, annual years of life lost (YLLs), and health adjusted life years (HALYs). We used the 2000 US Medical Expenditure Panel Survey to derive quality of life estimates by income and age, the 1990-1992 US National Health Interview Survey linked to National Death Index data through the end of 1995 to derive mortality risks by income and by age, and 2000 US mortality data from the National Center for Health Statistics to derive current mortality estimates for the US population by age-group. The bottom 80% of adult income earners' life expectancy is 4.3 years and 5.8 HALYs shorter

relative to those in the top 20% of earnings. This translates into the loss of 11 million YLLs and 17.4 million HALYs each year. Compared with persons living above the poverty threshold, those living below the poverty threshold live an average of 3.2 million fewer HALYs per year—a difference of 8.5 HALYs per individual between age 18 and death. The income-associated burden of disease appears to be a leading cause of morbidity and mortality in the US.

Mueser KT, Salyers MP, Rosenberg SD *et al.* Interpersonal trauma and posttraumatic stress disorder in patients with severe mental illness: demographic, clinical, and health correlates. *Schizophr Bull* 2004; 30(1):45-57. Notes: CORPORATE NAME: 5 Site Health and Risk Study Research Committee Abstract: This study's purpose was to evaluate the prevalence and correlates of posttraumatic stress disorder (PTSD) in persons with severe mental illness. Standardized assessments of interpersonal trauma and PTSD were conducted in 782 patients with severe mental illness receiving services in one of five inpatient and outpatient treatment settings. Analyses examined the prevalence of PTSD and the demographic, clinical, and health correlates of PTSD diagnosis. The overall rate of current PTSD in the sample was 34.8 percent. For demographic characteristics, the prevalence of PTSD was higher in patients who were younger, white, homeless, and unemployed. For clinical and health variables, PTSD was more common in patients with major mood disorders (compared to schizophrenia or schizoaffective disorders), alcohol use disorder, more recent psychiatric hospitalizations, more health problems, more visits to doctors for health problems, and more nonpsychiatric hospitalizations over the past year. The results support prior research documenting the high rates of PTSD in patients with severe mental illness and suggest that PTSD may contribute to substance abuse, psychiatric and medical comorbidity, and psychiatric and health service utilization.

Mujkic A, Vuletic G, Kozaric-Kovacic D. Evaluation of community based intervention for the protection of children from small arms and explosive devices during the war: observational study. *Croat Med J* 2002; 43(4):390-5.

Abstract: AIM: To evaluate the influence of a community-based intervention aimed at reducing the risk of unintentional injuries caused by small arms and explosive devices accessible to children during the 1991-1995 war in Croatia. METHOD: From May 5 to June 15 in 1994 and 1995, we performed a cross-sectional survey on exposure of the children in Croatia to different small arms and explosive devices, using specially prepared questionnaires. The survey was conducted in Dubrovnik-Neretva and Karlovac counties, where community-based intervention was carried out, and Lika-Senj and Sisak-Moslavina counties, where only national intervention was

implemented. The sample included a total of 5,317 parents and 2,581 children. The response rate was 98%. All participants were asked to give answers according to current situation. RESULTS: Approximately a third of children in the counties without community-based intervention and a fifth in the counties with community-based intervention could access small arms and explosive devices at home. Boys were more exposed than girls ( $p=0.001$ ). In the communities with community-based intervention, children were less exposed to the devices, such as small-arms, hand grenades, and explosives, which were the main cause of injuries. In 1994, parents in counties without community-based intervention handled weapons in front of their children in 45% cases vs 31% of those in the counties with community-based intervention ( $p<0.001$ ). In 1995, the percentages were 44 and 32, respectively ( $p<0.001$ ). CONCLUSION: Although it is impossible to quantify the exact amount of risk reduction due to health intervention alone, community-based intervention reduced the exposure of children to weapons.

Mukadam S, Gilles EE. Unusual inflicted hot oil burns in a 7-year-old. *Burns* 2003; 29(1):83-6. Abstract: Pediatric burn injuries occur not infrequently as the result of abuse. While the majority of these burns are inflicted scald burns, those due to contact or contact/scald mechanisms may present diagnostic challenges. A child with unusual combined contact and scald burns caused by a metal spatula heated in hot cooking oil is described. The odd pattern of healed injury limited the initial diagnosis to inflicted healing burns. Despite the initial lack of disclosure, an inflicted etiology was supported by clearly delineated margins, macular lesions with hyper-pigmented rims and variegated central regions. Additional findings of numerous adult bites and bruises provided adjunctive support for an inflicted etiology. Aspects of this case are atypical for the usual demographics of a burn victim. This case extends the known presentations of inflicted contact/scald burns.

Mullins SM, Suarez M, Ondersma SJ, Page MC. The impact of motivational interviewing on substance abuse treatment retention: a randomized control trial of women involved with child welfare. *J Subst Abuse Treat* 2004; 27(1):51-8. Abstract: Previous studies have supported the efficacy of Motivational Interviewing (MI) in increasing treatment engagement and retention among people with substance abuse disorders. However, few studies have assessed the impact of MI with coerced populations,

particularly women referred to drug abuse treatment by child welfare due to prenatal drug use. Seventy-one such women who used drugs during pregnancy were randomly assigned to either receive three MI sessions or to watch two educational videos and participate in a home visit. Treatment retention group attendance and random urine analysis results were evaluated in these women during the first 8 weeks of treatment. No differences were found between the two conditions on these variables. Possible reasons for these negative findings are discussed, as are ideas for future research with coerced populations.

Mulvihill A, Buncic JR. Vertical sensory nystagmus associated with intraocular haemorrhages in the shaken baby syndrome. *Eye* 2004; 18(5):545-6.

Munjanja SP. Ethics in reproductive health: clinical issues in Zimbabwe. *Cent Afr J Med* 2001; 47(6):159-63. Notes: GENERAL NOTE: KIE: 14 refs. GENERAL NOTE: KIE: KIE Bib: reproduction Abstract: Reproductive health can present health practitioners with ethical problems because of the complex interaction between cultural practices, the laws of the country and individual personal preferences. In particular, the problems of pregnancy, sexually transmitted infections, family planning, sexual violence, and domestic abuse require a good knowledge of the laws of the country and the culture in which they operate. The practitioner should at all times respect the patient's autonomy and serve their best interests, whilst keeping in mind the legitimate interest of their partners, spouses, parents or guardians.

Munoz Cobos F, Martin Carretero ML, Vivancos Escobar D, Blanca Barba F, Rodriguez Carrion T, Ruiz Ramos M. [Improving care for victims of domestic violence. Impact of a priority intervention]. *Aten Primaria* 2001; 28(4):241-8.

Abstract: OBJECTIVE: To evaluate the impact of a priority intervention in the care given to women who are victims of domestic violence and their children. DESIGN: Non-randomised intervention study. SETTING: Urban health centre. PATIENTS: Women and children living at a reception centre for families suffering domestic violence and who had clinical records opened at the health centre. Pre-intervention group (December 1997-July 1999): 36 women, 70 children. Post-intervention group (August 1999-June 2000): 35 women and 41 children. Interventions. Allocation to a single family doctor and paediatrician. Elimination of bureaucratic obstacles and prioritised care. Social/family assessment by the social worker. Preferential inclusion in programmes: Women: family planning, hepatitis B vaccination, pregnancy control, early diagnosis of breast cancer (women > 50), same for cervical cancer. Children: child health (< 5) (priority activities: psychomotor development and somatometry) and vaccinations. This intervention

started in August 1999. MEASUREMENTS AND MAIN RESULTS: Measurement of the impact of the intervention: bivariate analysis through Chi<sup>2</sup> test for qualitative variables and Student's t test and U Mann-Whitney test for quantitative variables (alpha 0.05) in the pre- and post-intervention groups. Statistically significant differences in participation were detected between the pre- and post-intervention groups in the following activities: number of visits to programmes (0.49, SD 0.95; 1.01, SD 1.24, respectively), social and family assessment (83%/100%), family planning (14%/51.4%), hepatitis B vaccination (19%/48.7%), early cervical cancer diagnosis (0/25.7%), child health (33.4%/70%), vaccinations (26.34%/64%), somatometric assessment (25%/100%) and psychomotor development assessment (41.6%/94%). CONCLUSIONS: Prioritised intervention in families that are victims of domestic violence improves their participation in preventive activities.

Munro VE. Square pegs in round holes: the dilemma of conjoined twins and individual rights. *Soc Leg Stud* 2001; 10(4):459-82.

Notes: GENERAL NOTE: KIE: Munro, Vanessa E

GENERAL NOTE: KIE: KIE Bib: patient care/minors; personhood

Abstract: The judgment in the English Court of Appeal case of *Re A (Conjoined Twins: Surgical Separation)* highlights forcefully the highly individualistic and abstract assumptions that commonly shape the deployment of rights discourse in liberal legal adjudication. Forced by the all-or-nothing nature of this discourse into a dilemma between perceiving of the twins as separate right-bearers or perceiving of the stronger twin, Jodie, as the singular right-bearer and of Mary, her weaker sibling, as a non-legal entity, the court chose the former option. Perceiving of the twins as distinct and equal legal persons forced the court to employ a balancing of incommensurate interests, implicitly accepting a utilitarian analysis within the strongly deontological confines of law and medicine. The implications of this turn towards utilitarianism are significant. Within the confines of this article, it will be argued, however, that these implications are avoidable if the law concedes a more flexible approach to the dominant notion of the distinct and autonomous right-bearer.

Muntaner C, Lynch JW, Hillemeier M *et al.* Economic inequality, working-class power, social capital, and cause-specific mortality in wealthy countries. *Int J Health Serv* 2002; 32(4):629-56.  
Abstract: This study tests two propositions from Navarro's critique of the social capital literature: that social capital's importance has been exaggerated and that class-related political factors, absent from social epidemiology and public health, might be key determinants of population health. The authors estimate cross-sectional associations between economic

inequality, working-class power, and social capital and life expectancy, self-rated health, low birth weight, and age- and cause-specific mortality in 16 wealthy countries. Of all the health outcomes, the five variables related to birth and infant survival and nonintentional injuries had the most consistent association with economic inequality and working-class power (in particular with strength of the welfare state) and, less so, with social capital indicators. Rates of low birth weight and infant deaths from all causes were lower in countries with more "left" (e.g., socialist, social democratic, labor) votes, more left members of parliament, more years of social democratic government, more women in government, and various indicators of strength of the welfare state, as well as low economic inequality, as measured in a variety of ways. Similar associations were observed for injury mortality, underscoring the crucial role of unions and labor parties in promoting workplace safety. Overall, social capital shows weaker associations with population health indicators than do economic inequality and working-class power. The popularity of social capital and exclusion of class-related political and welfare state indicators does not seem to be justified on empirical grounds.

Murray L, Woolgar M, Murray J, Cooper P. Self-exclusion from health care in women at high risk for postpartum depression. *J Public Health Med* 2003; 25(2):131-7.

Abstract: **BACKGROUND:** A significant proportion of women who are vulnerable to postnatal depression refuse to engage in treatment programmes. Little is known about them, other than some general demographic characteristics. In particular, their access to health care and their own and their infants' health outcomes are uncharted. **METHODS:** We conducted a nested cohort case-control study, using data from computerized health systems, and general practitioner (GP) and maternity records, to identify the characteristics, health service contacts, and maternal and infant health outcomes for primiparous antenatal clinic attenders at high risk for postnatal depression who either refused (self-exclusion group) or else agreed (take-up group) to receive additional Health Visiting support in pregnancy and the first 2 months postpartum. **RESULTS:** Women excluding themselves from Health Visitor support were younger and less highly educated than women willing to take up the support. They were less likely to attend midwifery, GP and routine Health Visitor appointments, but were more likely to book in late and to attend accident and emergency department (A&E). Their infants had poorer outcome in terms of gestation, birthweight and breastfeeding. Differences between the groups still obtained when age and education were taken into account for midwifery contacts, A&E attendance and gestation; the difference in the initiation of breast feeding was attenuated, but not wholly explained, by age and education. **CONCLUSION:** A subgroup of psychologically vulnerable child-bearing women are at particular risk for poor access to health care and adverse infant outcome. Barriers to take-up of services need to be understood in order better to deliver care.

very instrumental in both decreasing and preventing bullying behaviors.

Mustillo S, Worthman C, Erkanli A, Keeler G, Angold A, Costello EJ. Obesity and psychiatric disorder: developmental trajectories. *Pediatrics* 2003; 111(4 Pt 1):851-9.

Abstract: **OBJECTIVES:** To identify age-related trajectories of obesity from childhood into adolescence, and to test the association of these trajectories with the development of psychiatric disorders (conduct disorder, oppositional defiant disorder, attention-deficit/hyperactivity disorder, substance abuse, depression, and anxiety). **METHODS:** White children (N = 991) 9 to 16 years old from the Great Smoky Mountains Study, a representative sample of rural youth, were evaluated annually over an 8-year period for height, weight, psychiatric disorder, and vulnerabilities for psychiatric disorder. Longitudinal analyses on the repeated measures data were conducted using developmental trajectory models and generalized estimating equation models. **RESULTS:** Obesity was 3 to 4 times more common than expected from national rates using Centers for Disease Control and Prevention 2000 criteria. Four developmental trajectories of obesity were found: no obesity (73%), chronic obesity (15%), childhood obesity (5%), and adolescent obesity (7%). Only chronic obesity was associated with psychiatric disorder: oppositional defiant disorder in boys and girls and depressive disorders in boys. **CONCLUSIONS:** In a general population sample studied longitudinally, chronic obesity was associated with psychopathology.

Myer L, Abdool Karim SS, Lombard C, Wilkinson D. Treatment of maternal syphilis in rural South Africa: effect of multiple doses of benzathine penicillin on pregnancy loss. *Trop Med Int Health* 2004; 9(11):1216-21.

Abstract: **OBJECTIVES:** Despite few data, the treatment of syphilis in pregnant women using a single dose of benzathine penicillin is the standard of care in many resource-poor settings. We examined the effect of various doses of benzathine penicillin on pregnancy loss among women with a positive Rapid Plasma Reagin (RPR) test result in a rural South African district. **METHODS:** All pregnant women making their first antenatal care visit during pregnancy were screened for syphilis using the RPR test. Those testing positive were counselled to receive three weekly doses of benzathine penicillin, and received a partner notification card. Pregnancy outcomes were determined from facility records or home visits where necessary. **RESULTS:** Of 8917 women screened, 1043 (12%) had reactive syphilis serology; of those with titre data available, 30% had titres of 1:8 or greater. While 41% (n = 430) of women received all three doses as counselled, 30% (n = 312) received only one dose, and 20% (n = 207) did not return to the clinic to receive treatment. Among the 947 women with pregnancy

Muscari ME. Sticks and stones: the NP's role with bullies and victims. *J Pediatr Health Care* 2002; 16(1):22-8. Abstract: Bullying is a worldwide problem that can create negative lifelong consequences for both bullies and victims. Victims of bullies can suffer from low self-esteem, depression, and anxiety, all problems that may carry into adulthood. The academic progress of victims may be impaired, and they may find themselves isolated because their peers fear losing status or being bullied themselves. Bullies may develop conduct disorders and delinquent behaviors during their teen years, as well as serious antisocial and criminal behavior in adulthood. The majority of bullies remain bullies throughout their lives, cherishing the power and control over others that their behavior evokes. Nurse practitioners play a critical role in the identification of both bullies and victims and can be

- outcome data available, there were 17 miscarriages and 48 perinatal deaths observed. There was a strong trend towards reduced risk of pregnancy loss among women receiving multiple doses of penicillin (adjusted OR for perinatal mortality for each additional dose received, 0.63; 95% CI, 0.48-0.84). CONCLUSIONS: While this association requires further investigation, these results suggest that there may be substantial benefit to providing multiple doses of benzathine penicillin to treat maternal syphilis in this setting.

- Nagelkerke NJ, Jha P, de Vlas SJ *et al.* Modelling HIV/AIDS epidemics in Botswana and India: impact of interventions to prevent transmission. *Bull World Health Organ* 2002; 80(2):89-96. Abstract: OBJECTIVE: To describe a dynamic compartmental simulation model for Botswana and India, developed to identify the best strategies for preventing spread of HIV/AIDS. METHODS: The following interventions were considered: a behavioural intervention focused on female sex workers; a conventional programme for the treatment of sexually transmitted infections; a programme for the prevention of mother-to-child transmission; an antiretroviral treatment programme for the entire population, based on a single regimen; and an antiretroviral treatment programme for sex workers only, also based on a single regimen. FINDINGS: The interventions directed at sex workers as well as those dealing with sexually transmitted infections showed promise for long-term prevention of human immunodeficiency virus (HIV) infection, although their relative ranking was uncertain. In India, a sex worker intervention would drive the epidemic to extinction. In Botswana none of the interventions alone would achieve this, although the prevalence of HIV would be reduced by almost 50%. Mother-to-child transmission programmes could reduce HIV transmission to infants, but would have no impact on the epidemic itself. In the long run, interventions targeting sexual transmission would be even more effective in reducing the number of HIV-infected children than mother-to-child transmission programmes. Antiretroviral therapy would prevent transmission in the short term, but eventually its effects would wane because of the development of drug resistance. CONCLUSION: Depending on the country and how the antiretroviral therapy was targeted, 25-100% of HIV cases would be drug-resistant after 30 years of use.
- Nainan OV, Armstrong GL, Han XH, Williams I, Bell BP, Margolis HS. Hepatitis a molecular epidemiology in the United States, 1996-1997: sources of infection and implications of vaccination policy. *J Infect Dis* 2005; 191(6):957-63. Abstract: BACKGROUND: The genetic relatedness of hepatitis A virus (HAV) isolates was determined to identify possible infection sources for case patients in the Sentinel Counties Study of Acute Viral Hepatitis. METHODS: A 315-nucleotide segment of the VP1-P2 region of the HAV genome was amplified and sequenced from serum of case patients and analyzed together with risk-factor data. RESULTS: Of 508 HAV-RNA-positive case patients, 449 (88.4%) were interviewed, and 255 (50.1%) reported  $\geq 1$  risk factor. Some 123 unique nucleotide sequence patterns (UNSPs) were identified--77 (62.6%) from only 1 case patient and the rest in 2-99 persons. Among international travelers, a single person was more often infected with a single type of UNSP (17/54 [31.5%]), compared with other case patients (48/393 [12.2%];  $P < .001$ ). UNSPs from travelers to Mexico (33/37 [89.2%]) clustered with those from Hispanic children (47/49 [95.9%]). Of 119 men who had sex with men, 96 (80.7%) had the same or similar UNSPs, which were also found in 37 men and 10 women with no identified infection source. CONCLUSION: HAV is often transmitted within networks of persons with similar risk factors, which may be the infection source for others in the community.
- Nair MK. Child abuse. *Indian Pediatr* 2004; 41(4):319-20.
- Nandi S, Kumar R, Ray P, Vohra H, Ganguly NK. Group A streptococcal sore throat in a periurban population of northern India: a one-year prospective study. *Bull World Health Organ* 2001; 79(6):528-33. Abstract: OBJECTIVE: To estimate the incidence and risk factors of group A streptococcus (GAS) sore throat among school-aged children living in a periurban slum area of Chandigarh, North India. METHODS: A total of 536 children aged 5-15 years from 261 families identified by a systematic random selection method were enrolled in the study. Episodes of sore throat were recorded through fortnightly home visits over a one-year period. The local vernacular (Hindi) terms gala kharab (bad throat) and khansi jukam (cough and cold) were used to identify symptoms of sore throat, and throat swab specimens were collected from children who had these symptoms on the day of the home visit. Bacterial culture was carried out and the isolation of GAS was confirmed using group-A-specific antiserum. FINDINGS: The incidences of sore throat and GAS sore throat were, respectively, 7.05 and 0.95 episodes per child-year. The incidence was higher in the following situations: among 11-year-olds, during the winter (November to January) and rainy (August)

months (a bimodal peak), among children living in houses where there was no separate room for the kitchen, and in homes that included a tobacco smoker. CONCLUSION: The results show that the incidence of GAS sore throat was related to age, season, and indoor air pollution.

Nansel TR, Craig W, Overpeck MD, Saluja G, Ruan WJ. Cross-national consistency in the relationship between bullying behaviors and psychosocial adjustment. *Arch Pediatr Adolesc Med* 2004; 158(8):730-6. Notes: CORPORATE NAME: Health Behaviour in School-aged Children Bullying Analyses Working Group

Abstract: OBJECTIVE: To determine whether the relationship between bullying and psychosocial adjustment is consistent across countries by standard measures and methods. DESIGN: Cross-sectional self-report surveys were obtained from nationally representative samples of students in 25 countries. Involvement in bullying, as bully, victim, or both bully and victim, was assessed. SETTING: Surveys were conducted at public and private schools throughout the participating countries. PARTICIPANTS: Participants included all consenting students in sampled classrooms, for a total of 113 200 students at average ages of 11.5, 13.5, and 15.5 years. MAIN OUTCOME MEASURES: Psychosocial adjustment dimensions assessed included health problems, emotional adjustment, school adjustment, relationships with classmates, alcohol use, and weapon carrying. RESULTS: Involvement in bullying varied dramatically across countries, ranging from 9% to 54% of youth. However, across all countries, involvement in bullying was associated with poorer psychosocial adjustment ( $P < .05$ ). In all or nearly all countries, bullies, victims, and bully-victims reported greater health problems and poorer emotional and social adjustment. Victims and bully-victims consistently reported poorer relationships with classmates, whereas bullies and bully-victims reported greater alcohol use and weapon carrying. CONCLUSIONS: The association of bullying with poorer psychosocial adjustment is remarkably similar across countries. Bullying is a critical issue for the health of youth internationally.

Narang DS, Contreras JM. The relationships of dissociation and affective family environment with the intergenerational cycle of child abuse. *Child Abuse Negl* 2005; 29(6):683-99. Abstract: OBJECTIVE: The purpose was to test a model that may explain how physically abused children become physically abusive parents. It was predicted that when the family's affective environment is uncohesive, unexpressive, and conflictual, a history of abuse experiences would be associated with elevated dissociation. It was hypothesized that dissociation would mediate between a childhood history of abuse and the current potential to be physically abusive.

METHOD: Abuse history, affective environment in the family-of-origin, dissociation, and abuse potential were assessed in a sample of 76 mothers with elementary school-age children. RESULTS: Predictions were supported. Affective Family Environment moderated the relation between abuse history and dissociation, with abuse history relating to greater dissociation primarily when the family environment was conflictual, uncohesive and unexpressive. Further, dissociation significantly mediated the relation between abuse history and abuse potential ( $Z = 2.19, p < .05$ ). CONCLUSIONS: Dissociation's strong association with abuse potential may partially explain why only some abused children later perpetuate the cycle of abuse, as those who are not dissociative into adulthood are likely to have lower abuse potential, in contrast to those displaying elevated dissociation. The extent of the dissociation may depend on the affective family environment in which the abuse took place.

Narayanasamy A, Owens J. A critical incident study of nurses' responses to the spiritual needs of their patients. *J Adv Nurs* 2001; 33(4):446-55. Notes: GENERAL NOTE: KIE: 35 refs. GENERAL NOTE: KIE: KIE Bib: patient care; professional patient relationship Abstract: AIMS OF STUDY: The aims of the study were to carry out a critical incident study to: (1) Describe what nurses consider to be spiritual needs; (2) Explore how nurses respond to the spiritual needs of their patients; (3) Typify nurses' involvement in spiritual dimensions of care; (4) Describe the effect of nurses' intervention related to spiritual care. BACKGROUND: In the caring professions a focus on individuals as bio-psychological-spiritual beings is gaining recognition and this notion is based on the premise that there should be a balance of mind, body and spirit for the maintenance of health in a person (Stoll 1979). Emerging research highlights the importance of spiritual care in nursing and suggests that there is scope for improving this dimension of care in order to improve the quality of life for many patients. However, there is very little evidence about how nurses respond to the spiritual needs of their patients. Therefore the purpose of this study was to map by critical incident techniques how nurses construct and respond to patients' spiritual needs in a variety of clinical settings. METHODS: Critical incidents were obtained from 115 nurses. The data from these incidents were subjected to content analysis and categories were developed and described. The emerging categories were subjected to peer reviews to ensure reliability and validity of findings. FINDINGS: The findings suggest that there is confusion over the notion of spirituality and the nurse's role related to spiritual care. A variety of approaches to spiritual care emerged in this study from the critical incidents derived from nurse respondents. These were categorized as 'personal', 'procedural', 'culturalist' or 'evangelical'. There was an overwhelming consensus

that patients' faith and trust in nurses produces a positive effect on patients and families, and nurses themselves derived satisfaction from the experience of giving spiritual care. In this respect, spiritual care interventions promote a sense of well-being in nurses as well as being a valuable part of total patient care. CONCLUSION: The study concluded that there is scope for developing an ideal model of spiritual care using the critical incident data from this study.

Narbona J, Crespo N. [Developmental amnesias]. *Rev Neurol* 2002; 34 Suppl 1:S110-4. Abstract: OBJECTIVE: The literature on clinical and physiopathologic characteristics of the spectrum of memory disorders in childhood is reviewed in this article. DEVELOPMENT: There are only a few detailed reports of permanent specific memory disorders in children. Early anoxic ischaemic bihippocampal injuries can cause a selective permanent impairment of episodic daily life memory with preservation of semantic learning and general intelligence; this dissociation has been related to partial hippocampal damage whilst the entorhinal, parahippocampal and prefrontal cortices, which are critical to systematized memorizing and work memory, keep normal. Biological psychiatry research has shown that early childhood amnesias after psychological maltreatment or abuse could be related to damage in neuronal systems which support memory, caused by glutamatergic cascade. Both severe bilateral hippocampal sclerosis (also mediated by toxic neurotransmitters) in early malignant epilepsies, and massive bilateral damage of mesial temporal lobes due to herpes virus encephalitis or Reye's syndrome, cause severe amnesic deficits, frequently accompanied by absence of any language development and autism with features of Kluver-Bucy syndrome. There are also on record some examples of Korsakoff's syndrome in children with midfossa tumors. CONCLUSIONS: All types of classical amnesias described in adults have been observed in children. Developmental amnesias are probably more frequent than currently presumed. It must be paid special attention to selective autobiographical memory impairments in individuals who underwent a partial bihippocampal damage in perinatal or early postnatal periods; they are to be distinguished from, although it may coexist with, other clinical situations such as attention deficit disorder or semantic pragmatic disorder.

Nassogne MC, Sharrard M, Hertz-Pannier L *et al.* Massive subdural haematomas in Menkes disease mimicking shaken baby syndrome. *Childs Nerv Syst* 2002; 18(12):729-31. Abstract: INTRODUCTION: Menkes disease is an X-linked inherited disorder of intestinal copper absorption resulting in copper deficiency. Cardinal features include hair abnormalities, facial dysmorphism, severe neurological impairment, hypothermia, arterial anomalies, bone abnormalities and a fatal outcome.

CASE REPORT: We present a case of Menkes disease complicated by progressive macrocephaly following the development of massive subdural haematomas. These lesions associated with femoral metaphyseal spurs could be confused with nonaccidental injury such as that seen in the shaken baby syndrome. DISCUSSION: This case emphasises that Menkes disease, like glutaric aciduria type 1, should be included in the differential diagnosis of unexplained subdural haematomas and neurological deficits in infants.

Navaie-Waliser M, Misener M, Mersman C, Lincoln P. Evaluating the needs of children with asthma in home care: the vital role of nurses as caregivers and educators. *Public Health Nurs* 2004; 21(4):306-15. Abstract: To date, few evaluations have examined issues specific to children's asthma management in their homes. This study examined the characteristics, risk factors, and needs of children with asthma, and the impact of home health nurses on improving parents'/family caregivers' knowledge about asthma triggers and management. The medical records of children,  $\leq 19$  years, residing in New York City, who were admitted to home care with asthma in 1999 ( $n = 1,007$ ) were reviewed retrospectively to collect a wide range of data. The majority of children with asthma in home care were  $\leq 5$  years, male, racial/ethnic minorities, and hospital referred. Approximately one in four children with asthma suffered from additional comorbidities. Home environmental triggers included dust/dust mites, animal dander, mold, perfumes/detergents, and cigarette smoke. Notable psychosocial triggers were family tensions, physical activity, anxiety/stress, and friends/peer pressure. Most parents/family caregivers had inadequate knowledge about recognition of asthma attacks and its triggers and management. Discharge assessments suggested that home health nurses can help improve caregivers' knowledge about asthma management. Children with asthma in home care have diverse needs, receive few nurse home visits, and have parents/family caregivers in need of more intensive education on asthma symptom recognition and management.

Navarro V, Borrell C, Benach J *et al.* The importance of the political and the social in explaining mortality differentials among the countries of the OECD, 1950-1998. *Int J Health Serv* 2003; 33(3):419-94. Abstract: This article analyzes (within the conceptual frame defined in the previous article) the impact of political variables such as time of government by political parties (social democratic, Christian democratic or conservative, liberal, and ex-dictatorial that have governed the OECD countries during the 1950-1998 period) and their electoral support on (1) redistributive policies in the labor market and in the welfare state; (2) the income inequalities measured by Theil and Gini indexes; and (3) health indicators, such as infant mortality and life expectancy. This analysis is

carried out statistically by a bivariate and a multivariate analysis (a pooled cross-sectional study). Both analyses show that political variables play an important role in defining how public and social policies determine the levels of inequalities and affect the level of infant mortality. In general, political parties more committed to redistributive policies, such as social democratic parties, are the most successful in reducing inequalities and improving infant mortality. Less evidence exists, however, on effects on life expectancy. The article also quantifies statistically the relationship between the political and the policy variables and between these variables and the dependent variables--that is, the health indicators.

Navratil F. [Genital infections in prepubertal girls]. *Ther Umsch* 2002; 59(9):475-9. Abstract: Vulvitis and vulvovaginitis are the most common gynecologic complaint in prepubertal girls. The frequently observed therapeutic failures are due mainly to lack of knowledge of the characteristics of this age group, of age and development in appropriate diagnostic procedures and of therapeutic measures similar to those in the adult female patient. Prepubertal girls are anatomically, physiologically and behaviorally at relative risk for vulvovaginitis. Symptoms include pruritus, genital pain, "vulvar dysuria" and discharge. History taking and a general pediatric examination are mandatory, thereafter an age appropriate careful anogenital examination should follow. It requires time, patience and knowledge of the different non traumatizing examination techniques. The findings in girls with vulvovaginitis are variable and erythema, excoriations and discharge can be found. The genital inspection and the use of microscopy and microbiologic studies are helpful in planning an appropriate therapy. The majority of vulvovaginal infections in children are nonspecific but they can also be caused by specific organisms and are mostly bacterial. Yeast infections are not found in otherwise healthy prepubertal girls. The therapeutic approach consists of improved anogenital hygiene, sitz/tub baths and use of non irritating soaps. However if an abnormal population of bacteria is present antimicrobial therapy should be considered. Reassurance and a review of preventive methods are crucial in the management of girls with vulvovaginitis.

Navratil F. [Sexual abuse in adolescence: patient assessment, necessity and meaning of the physical examination]. *Gynakol Geburtshilfliche Rundsch* 2003; 43(3):146-51. Abstract: The objective of this paper is to report on the characteristics of sexual abuse in adolescence, on the medical evaluation and interpretation of findings and on the necessity of a multidisciplinary intervention. Sexual abuse is a common problem affecting children and adolescents, males and females of any age or socio-economic class. 10-22% of adolescents are victims of sexual abuse. They engage more frequently in risk-taking behaviours, such as early sexual activity,

unprotected sexual contact with multiple partners (risk of sexually transmitted diseases, of an unwanted pregnancy), substance abuse, delinquency, school failure or suicide. Professionals who deal with adolescents should be aware of the devastating medical and psychosocial sequelae of sexual abuse and should be able to recognize it, incorporating questions regarding victimization into the psycho-social or sexual history. A medical examination, including an external anogenital inspection and in selected cases a pelvic examination, should always be performed. It is important to acknowledge that normal anogenital findings do not exclude sexual abuse and that a multidisciplinary medical-psychosocial evaluation is mandatory.

Needlman R, Toker KH, Dreyer BP, Klass P, Mendelsohn AL. Effectiveness of a primary care intervention to support reading aloud: a multicenter evaluation. *Ambul Pediatr* 2005; 5(4):209-15. Abstract: OBJECTIVE: Failure to read at grade level predicts life-long economic and social disability. Early exposure to reading aloud may prevent reading problems. This study seeks to determine whether institution of Reach Out and Read (ROR) programs is associated with increased reading aloud in a national sample. DESIGN: Before-after intervention study: separate convenience samples were studied before and after institution of ROR programs at multiple sites. PARTICIPANTS AND SETTING: A convenience sample of parents of children age 6-72 months seeking routine health care at 19 clinical sites in 10 states. INTERVENTIONS: The ROR model incorporates anticipatory guidance about reading aloud and distribution of free picture books at health supervision visits from 6 months through 5 years as well as reading aloud in the waiting room. MAIN OUTCOME MEASURES: Parents were interviewed about their attitudes and practices related to reading aloud, using questions drawn from validated instruments. RESULTS: The sample included 1647 subjects (730 intervention, 917 comparison). After controlling for multiple potential confounding factors, significant associations were found between exposure to ROR and reading aloud as a favorite parenting activity (Adjusted Odds Ratio [AOR] 1.6,  $P < .001$ ); reading aloud at bedtime (Adjusted Odds Ratio [AOR] 1.5,  $P < .001$ ); reading aloud 3 or more days per week (AOR 1.8,  $P < .001$ ); and ownership of  $>$  or  $=$  10 picture books (AOR 1.6,  $P < .001$ ). CONCLUSIONS: In a national sample, implementation of ROR programs was associated with increased parental support for reading aloud. This study provides evidence of the effectiveness of a primary care intervention strategy to promote reading aloud to young children.

Neggens Y, Goldenberg R, Cliver S, Hauth J. Effects of domestic violence on preterm birth and low birth weight. *Acta Obstet Gynecol Scand* 2004; 83(5):455-60.

Abstract: **BACKGROUND:** Domestic violence is increasingly recognized as a potentially modifiable risk factor for adverse pregnancy outcomes. This study was conducted to evaluate the relationship between abuse during pregnancy or within the last year and low birth weight and preterm birth. **METHODS:** From 1997 to 2001, 3149 low income, relatively low-risk pregnant women (82% African-American) participated in this prospective study. The Abuse Assessment Screen, a validated screening tool, which assesses emotional, physical or sexual abuse, injuries due to physical abuse and physical abuse in the index pregnancy, was filled out by 3103 women. **RESULTS:** Of the women screened, 26.6% reported emotional abuse, 18.7% reported physical abuse in the past year and 10.3% women reported being beaten, bruised, threatened with a weapon or being permanently injured. Abuse during pregnancy was reported by 5.9% of the women. Low birth weight and preterm birth occurred in 10.9% and 10.2% of the pregnant women, respectively. Logistic regression analyzes indicated that injury due to physical abuse within the past year was significantly associated with both preterm birth [adjusted odds ratio (AOR) = 1.6, 95% confidence interval (CI) = 1.1-2.3] and low birth weight (AOR = 1.8, 95% CI = 1.3-2.5) after adjusting for other covariates. The mean birth weight of infants born to women who were injured due to physical abuse was significantly lower (-75.2 g,  $p = 0.04$ ) than the mean birth weight of infants of women who were not injured. **CONCLUSION:** These results indicate that in our population, injuries resulting from physical abuse are associated with both low birth weight and preterm birth.

Nelson S. Your body tells the truth. *Ment Health Today* 2003; 20-3.

Nemeth L, O'Briain DS, Puri P. Demonstration of neuronal networks in the human upper urinary tract using confocal laser scanning microscopy. *J Urol* 2001; 166(1):255-8.

Abstract: **PURPOSE:** To our knowledge innervation of the upper urinary tract and its role in motility and sensation are not clearly understood. The whole mount preparation technique provides 3-dimensional (D) morphology of the innervation and its relationship of branching and interconnecting nerve fibers to each other and to the neighboring tissues. Confocal laser scanning microscopy provides dramatic optical advantages for detecting 3-D structures in thick specimens. We investigated the distribution and morphology of the neuronal structures in the human upper urinary tract using the whole mount preparation technique and confocal laser scanning microscopy. **MATERIALS AND METHODS:** Whole mount preparations of the human renal pelvis and ureter were stained by standard immunohistochemical method using various neuronal markers (protein gene product 9.5, neuron specific enolase and neurofilament). The 3-D architecture of the specimens was investigated with the help of confocal laser scanning microscopy. **RESULTS:** We detected 2 mesh-like neuronal networks or plexus in the human upper urinary tract. The first and more prominent plexus was located in the submucosa between the lamina propria and tunica muscularis, and the second neuronal network was found between the smooth muscle fibers of the ureteral wall. There were frequent interconnections between the 2 networks in the ureteral wall. **CONCLUSIONS:** To our knowledge our study shows for the first time that there are 2 well formed mesh-like neuronal plexus in the human upper urinary tract. Our findings suggest that the autonomic nervous system of the human upper urinary tract may have a significant role in the propagation, coordination and modulation of ureteropelvic peristalsis.

Nemets B, Witztum E, Kotler M. [False memory syndrome: state of the art]. *Harefuah* 2002; 141(8):726-30, 760.

Abstract: The review describes the heated dispute on the present state of recovered traumatic memories. There are two main schools concerning the status of recovered memories of child abuse. One school believes in their authenticity unconditionally. Those who oppose the authenticity claim False Memory Syndrome's existence. They describe it as "a serious form of psychopathology characterized by strongly believed pseudomemories of childhood sexual abuse" and "condition in which a person's identity and interpersonal relationships are centered around a memory of traumatic experience which is objectively false but in which the person strongly believes". This review presents the allegations of both sides involved in the dispute, with updates of scientific and judicial

Nelms BC. Emotional abuse: helping prevent the problem. *J Pediatr Health Care* 2001; 15(3):103-4.

Nelson CA. Can we develop a neurobiological model of human social-emotional development? Integrative thoughts on the effects of separation on parent-child interactions. *Ann N Y Acad Sci* 2003; 1008:48-54. Abstract: After summarizing the main points raised in articles by Kaslow et al. and Plotsk, a number of questions that derive from these authors' work are listed. Additional questions are then posed, the answers to which will likely facilitate one's ability to translate animal models of child psychopathology into human terms. After summarizing the various advantages and disadvantages to models using mice, rats, and monkeys, several examples of recent research that have attempted to meld animal models with human studies are described.

- Neufeld S, Wright SM, Gaut J. Not raising a "bubble kid": farm parents' attitudes and practices regarding the employment, training and supervision of their children. *J Rural Health* 2002; 18(1):57-66. Abstract: This article explores farm parents' attitudes and practices regarding the employment, training and supervision of their children among a sample of 24 farm couples from southeastern Washington state. The goal was to gain a greater understanding of parental attitudes and practices in order to devise appropriate and meaningful efforts to improve the safety of children and adolescents involved in farm work. Demographic data regarding the farm families and their farm safety practices were collected through a short questionnaire, and parental attitudes and practices regarding the employment, training and supervision of their children were explored through open-ended, semi-structured interviews. The results suggest that farm parents have developed a logical and consistent set of beliefs and attitudes regarding the employment, training, and supervision of their children that is based in part on the belief that farm work is highly beneficial to their children's development. Safety interventions to reduce childhood farm injuries will have to acknowledge farm work as important and beneficial for children in order to maintain legitimacy and credibility. Nevertheless, because farm parents' practices regarding their children's employment reflect cultural beliefs and values regarding children and child-rearing, some recommended safety guidelines will be difficult to implement.
- Newcomb MD, Locke TF. Childhood adversity and poor mothering: consequences of polydrug abuse use as a moderator. *Addict Behav* 2005; 30(5):1061-4. Abstract: Drug abuse consequences have been typically examined as a direct or main effect on various later outcomes. Drug abuse may also serve as a consequence that alters (moderates) critical developmental trajectories. This study examined the relationship between childhood adversity factors (parent alcohol and drug-related problems, childhood maltreatment) and future parenting practices through an analysis of the moderating effects of polydrug problems. Data from a community sample of mothers was divided into two groups based on the median split level of polydrug problems (alcohol, marijuana, cocaine) that they reported (low, N=123; high, N=114). Confirmatory factor models (CFAs) were developed for the two groups and compared with multiple group analyses (MGAs). Results revealed that mothers who had parents with alcohol or drug-related problems were more likely to become poor parents, if they themselves used drugs and had problems related to drug use.
- Newman BS, Dannenfels PL. Children's protective services and law enforcement: fostering partnerships in investigations of child abuse. *J Child Sex Abus* 2005; 14(2):97-111. Abstract: Although collaboration in child abuse investigations has been emphasized since 1974, barriers, including role conflicts and organizational differences, have often been reported. This study describes the process of collaboration based on the perceptions of investigators working with a Child Advocacy Center. Telephone interviews were conducted with 290 child protective service workers and law enforcement officers from 28 child advocacy centers in 20 different states. Respondents identified barriers to the process of collaboration such as conflicts over case control and facilitators including co-housing and cross-training. Conditions that should contribute to successful collaboration are discussed.
- Newman JD, Sheehan KM, Powell EC. Screening for intimate-partner violence in the pediatric emergency department. *Pediatr Emerg Care* 2005; 21(2):79-83. Abstract: OBJECTIVE: The aims of this study were to determine the annual prevalence of intimate-partner violence (IPV) in an urban pediatric emergency department (ED) among mothers seeking care for their children, to examine the associations between IPV and family socioeconomic characteristics, triage time, and child's diagnosis, and to describe perceptions and preferences for IPV screening. METHODS: A confidential 15-item survey was completed by 451 women caretakers who were unaccompanied by a male partner in an urban pediatric ED associated with a children's hospital. Women were enrolled during 4-hour time blocks selected to represent ED use patterns during June and July 2002. Survey questions addressed experiences of IPV (physical or sexual violence and perception of safety) in the preceding year and preferences for IPV screening. We also collected information about the women's socioeconomic characteristics and the child's triage time and diagnosis. RESULTS: Fifty women reported IPV, an annual prevalence of 11%. Compared with white women, the relative risk of IPV among black women was 1.1 (95% confidence interval [CI], 1.0-1.2) and among Hispanic women was 1.1 (95% CI, 1.0-1.2). Compared with women who completed college, the relative risk of women who had not completed high school was 5.8 (95% CI, 2.0-26.4). We observed no association with poverty. Women who reported IPV more often sought care for their child in the evening (4-12 pm,  $\chi^2$ ,  $P < 0.01$ ); there was no association with the child's diagnosis. Most (75%) stated that IPV screening in the pediatric ED was appropriate. CONCLUSIONS: The annual prevalence of IPV in a pediatric ED is 11%. As socioeconomic and visit characteristics are imprecise in identifying women at risk, screening should include all women. Screening for IPV in the pediatric ED is

acceptable to women.

Newport DJ, Heim C, Bonsall R, Miller AH, Nemeroff CB.

Pituitary-adrenal responses to standard and low-dose dexamethasone suppression tests in adult survivors of child abuse. *Biol Psychiatry* 2004; 55(1):10-20. Abstract: BACKGROUND: Previous studies indicate that adverse childhood events are associated with persistent changes in corticotropin-releasing factor neuronal systems. Our aim was to determine whether altered glucocorticoid feedback mediates the neuroendocrine sequelae of childhood trauma. METHODS: Standard and low-dose dexamethasone suppression tests (DST) were performed in women with a history of child abuse (n=19), child abuse and major depression (n=16), major depression and no childhood trauma (n=10), and no history of mental illness or childhood trauma (n=19). Secondary analysis with posttraumatic stress disorder (PTSD) as the organizing diagnosis was also conducted. RESULTS: In the low-dose DST, depressed women with a history of abuse exhibited greater cortisol suppression than any comparator group and greater corticotropin suppression than healthy volunteers or nondepressed abuse survivors. There were no differences between nondepressed abuse survivors and healthy volunteers in the low-dose DST or between any subject groups in the standard DST. The PTSD analysis produced similar results. CONCLUSIONS: Cortisol supersuppression is evident in psychiatrically ill trauma survivors, but not in nondepressed abuse survivors, indicating that enhanced glucocorticoid feedback is not an invariable consequence of childhood trauma but is more related to the resultant psychiatric illness in traumatized individuals.

Nguyen M, Perry S, Parsonnet J. QuantiFERON-TB predicts tuberculin skin test boosting in U.S. foreign-born. *Int J Tuberc Lung Dis* 2005; 9(9):985-91. Abstract: SETTING: Santa Clara County, Northern California. OBJECTIVE: To characterize agreement of tuberculin skin test (TST) and QuantiFERON-TB (QFT) with repeated testing. DESIGN: Fifty-two subjects participating in an ongoing prospective study of infectious disease transmission were tested by TST and QFT at two home visits 3 months apart. Boosting was defined as reclassification of TST from negative to positive. Agreement and reproducibility of TST and QFT were assessed using kappa and McNemar statistics. RESULTS: Of 48 individuals completing all tests, 75% were foreign-born (92% Latin America) and 58% were BCG-vaccinated. Initial TST and QFT were positive in 13 (27%) and 21 (44%), respectively, with

an overall agreement of 67% (K = 0.29). Ten (29%) of 35 initial TST-negative reactions boosted, nine of whom were BCG-vaccinated subjects. Boosting occurred in eight (67%) of 12 subjects who were initially QFT-positive/TST-negative. Compared to the second TST, initial QFT had a relative post-test probability of 76% (95% CI 0.58-0.95); boosting accounted for 8/16 (50%) of initial testing discordances. CONCLUSION: Positive QFT in the setting of negative TST frequently anticipates a TST boost. This finding helps explain discordance between the two tests and may provide an alternative to serial TST testing.

Nguyen T, Malley R, Inkelis S, Kuppermann N. Comparison of prediction models for adverse outcome in pediatric meningococcal disease using artificial neural network and logistic regression analyses. *J Clin Epidemiol* 2002; 55(7):687-95.

Abstract: The objective of this study was to compare artificial neural network (ANN) and multivariable logistic regression analyses for prediction modeling of adverse outcome in pediatric meningococcal disease. We analyzed a previously constructed database of children younger than 20 years of age with meningococcal disease at four pediatric referral hospitals from 1985-1996. Patients were randomly divided into derivation and validation datasets. Adverse outcome was defined as death or limb amputation. ANN and multivariable logistic regression models were developed using the derivation set, and were tested on the validation set. Eight variables associated with adverse outcome in previous studies of meningococcal disease were considered in both the ANN and logistic regression analyses. Accuracies of these models were then compared. There were 381 patients with meningococcal disease in the database, of whom 50 had adverse outcomes. When applied to the validation data set, the sensitivities for both the ANN and logistic regressions models were 75% and the specificities were both 91%. There were no significant differences in any of the performance parameters between the two models. ANN analysis is an effective tool for developing prediction models for adverse outcome of meningococcal disease in children, and has similar accuracy as logistic regression modeling. With larger, more complete databases, and with advanced ANN algorithms, this technology may become increasingly useful for real-time prediction of patient outcome.

Ngwenya C. Access to health care services as a justiciable socio-economic right under the South African constitution. *Med Law Int* 2003; 6(1):13-23. Notes: GENERAL NOTE: KIE: 43 fn. GENERAL NOTE: KIE: KIE Bib: AIDS; health care/foreign countries; health care/rights Abstract: This commentary describes and analyses the decision of the Constitutional Court of South Africa in *Minister of Health and Others v Treatment Action*

Campaign and Others where the South African government was found to have violated the right of access to health care under the Constitution. Section 27(1) guarantees everyone the right of access to health care services. Section 27(2) imposes on the state a duty to take reasonable measures within its available resources to achieve the progressive realisation of this right. To the extent that government was unreasonably delaying access to patently affordable life-saving therapy for the prevention of mother-to-child transmission of HIV to a class of persons that was largely vulnerable and indigent, it is submitted that the case was correctly decided. However, there is little doubt that the decision, and in particular the prescriptive nature of the remedy granted by the Court and its budgetary implications, do not sit easily with a traditional notion of separation of powers between the judiciary on the one hand, and the executive and Parliament on the other. At the same time, it must be accepted that the remedy and its budgetary implications are an inevitable consequence of the inclusion of justiciable socio-economic rights in the Bill of Rights. The principles that were applied by the Court in determining the case were largely drawn from jurisprudence developed by organs under treaty bodies, and in particular the Committee on Economic, Social and Cultural Rights.

Nicholas SW, Abrams EJ. Boarder babies with AIDS in harlem: lessons in applied public health. *Am J Public Health* 2002; 92(2):163-5.

Nichols LA. The infant caring process among Cherokee mothers. *J Holist Nurs* 2004; 22(3):226-53. Abstract: The purpose of this study was to identify the social process of infant care among Cherokee mothers. Nineteen informants, who had an infant less than 2 years of age, were interviewed. The data were analyzed using the technique of constant comparative analysis. A social process of Indian infant care among Cherokee mothers was identified. Eight concepts emerged from data analysis. The first and principal concept, being a Cherokee mother, describes the functions of being an Indian mother in Cherokee society. The other seven concepts describe the patterns of cultural care the mothers provided to their infants. These included accommodating everyday infant care, accommodating health perspectives, building a care-providing consortium, living spiritually, merging the infant into Indian culture, using noncoercive discipline techniques, and vigilantly watching for the natural unfolding of the infant. Trustworthiness and credibility of the generated theory were evaluated through multiple measures.

Nicholson J, Biebel K. Commentary on "Community mental health care for women with severe mental illness who are parents" - The tragedy of missed opportunities: of missed opportunities: What providers can do. *Community Ment Health J* 2002; 38(2):167-72.

Abstract: Women and men who meet criteria for psychiatric disorder are likely to be parents. Many go undiagnosed and untreated, putting themselves and their children at risk of poor outcomes. Adults with mental illness may fear disclosing their status as parents; providers may not ask. Practices can be modified to promote the well being of parents with mental illness and their children.

Nicklas TA, Baranowski T, Baranowski JC, Cullen K, Rittenberry L, Olvera N. Family and child-care provider influences on preschool children's fruit, juice, and vegetable consumption. *Nutr Rev* 2001; 59(7):224-35.

Abstract: Children's intakes of fruit, juice, and vegetables (FJV) do not meet the recommended minimum of five daily servings, placing them at increased risk for development of cancer and other diseases. Because children's food preferences and practices are initiated early in life (e.g., 2-5 years of age), early dietary intervention programs may have immediate nutritional benefit, as well as reduce chronic disease risk when learned healthful habits and preferences are carried into adulthood. Families and child-care settings are important social environments within which food-related behaviors among young children are developed. FJV preferences, the primary predictor of FJV consumption in children, are influenced by availability, variety, and repeated exposure. Caregivers (parents and child-care providers) can influence children's eating practices by controlling availability and accessibility of foods, meal structure, food modeling, food socialization practices, and food-related parenting style. Much remains to be learned about how these influences and practices affect the development of FJV preferences and consumption early in life.

Nicolaidis C. The Voices of survivors documentary: using patient narrative to educate physicians about domestic violence. *J Gen Intern Med* 2002; 17(2):117-24. Abstract: This article describes a method of developing physician education materials using analysis of domestic violence patient experiences and patients' descriptions of their experiences. The process began with interviews of 21 domestic violence survivors, focusing on what they wanted to teach physicians. Qualitative analysis of these interviews identified 4 main themes regarding what survivors wanted physicians to understand about life in an abusive relationship: that domestic violence is universal, that it is more than just physical assaults, that it is all about power and control, and that it affects the entire family. Because what survivors wanted from physicians differed depending on where they were in their abusive

relationships, recommendations were developed for each of 5 common situations: when a patient may not yet recognize the abuse, when s/he may not be ready or able to disclose the abuse, when s/he chooses to remain in an abusive relationship, when s/he is seeking care for an acute assault, and when s/he has left the relationship but not yet healed. Interview excerpts representing each of the identified themes are used to create a 30-minute educational documentary. A written companion guide covers the traditional aspects of domestic violence education. In teaching about domestic violence or other health problems where it is difficult for physicians to understand their patients intuitively, an educator's most important role may be to direct learners to listen to the experience and wisdom of patients.

Nicoletti A. A role for the nurse practitioner. *J Pediatr Adolesc Gynecol* 2001; 14(2):101-2.

Nielsen LA, Mikkelsen SJ, Charles AV. [Chlamydia trachomatis and Neisseria gonorrhoeae infections in sexually abused children in Jutland]. *Ugeskr Laeger* 2002; 164(49):5806-9.  
Abstract: INTRODUCTION: At the Department of Forensic Medicine, University of Aarhus, Denmark, examinations are performed of children who are suspected of having been sexually abused. The medical forensic investigation aims at documenting sexual abuse if there are any physical findings. The presence of certain sexually transmitted diseases, which cannot be explained otherwise, may be such documentation. This article focuses on Chlamydia trachomatis and Neisseria gonorrhoeae, and the risk for the sexually abused child to contract these diseases. MATERIAL AND METHODS: Retrospectively, we went through the Institute's files from 1996 to 2000 concerning child abuse. Information about age, sex, cultures for Chlamydia trachomatis and for Neisseria gonorrhoeae, and the results of these cultures was registered. If the child had been cultured, the suspected perpetrator's age and gender were registered as well. The children were all between 0 and 15 years of age, and in all cases the suspicion of sexual abuse had led to reporting to the police. RESULTS: 295 girls and 41 boys were examined in the period from 1996 to 2000. A total of 100 cultures for Chlamydia trachomatis and 105 cultures for Neisseria gonorrhoeae were performed. Among the 111 children who were examined for Chlamydia trachomatis and/or Neisseria gonorrhoeae there were no positive results. In 102 cases the suspected perpetrator was known to be one or more men, and only in one case it was a women. The mean age of the suspected perpetrators was 35.4 years. DISCUSSION: The prevalence of Neisseria gonorrhoeae and Chlamydia trachomatis should reflect the prevalence in the group of perpetrators. Neisseria gonorrhoeae is uncommon outside Copenhagen, the capital of Denmark, whereas Chlamydia trachomatis is quite common. On this background, we had expected

some of the children to be infected with Chlamydia trachomatis. Therefore, the risk for sexually abused children to be infected with Chlamydia trachomatis or Neisseria gonorrhoeae is very low, depending on the kind of abuse and the perpetrator's possible risk behaviour, age, and gender. As a conclusion, only children with a clear indication should be tested for these sexually transmitted diseases.

Nievas F, Justicia F. Development of memory structures for homographs using pathfinder network representations. *Span J Psychol* 2003; 6(1):12-27.  
Abstract: Some studies with children have shown that there is no semantic priming at short stimulus onset asynchrony (SOA) in lexical decision and naming tasks for homographs. The predictions of spreading activation theories might explain this missing effect. There may be differences in children's and adults' memory structures. We have explored this hypothesis. The development of memory structure representations for homographs was measured by a Pathfinder algorithm. In Experiment 1, the three dependent variables were: the number of links in the network, closeness measures (C), and distances between nodes. Results revealed developmental differences in network structure representations in adults and children. In Experiment 2, results revealed that these differences were not due to the cohort effect. In Experiment 3, the relationship between associative strength, as measured by associative norms, and distances, as measured by Pathfinder algorithm, was explored. The results of these three experiments and empirical research from semantic priming experiments show that these differences in memory structure representations could be one of the sources of the missing semantic priming effect in children.

Nilsson C, Horgby K, Borres MP. [Increasing number of child abuse cases in Sweden--in accordance with reality?]. *Lakartidningen* 2001; 98(19):2298-301.  
Abstract: The number of police reports on child assault shows an increasing trend during the last two decades in Sweden. The purpose of this article is to present possible explanations. Increased awareness of child abuse, legislative reforms, changes in attitudes toward corporal punishment and violence in general, and changed routines within schools can explain the increasing trend in police reporting. An actual increase in the rate of child abuse is possible but less likely. Reports of increasingly violent behavior among young people must be taken seriously.

Nishida A, Sugiyama S, Aoki S, Kuroda S. Characteristics and outcomes of school refusal in Hiroshima, Japan: proposals for network therapy. *Acta Med Okayama* 2004; 58(5):241-9.  
Abstract: The authors conducted a study on children undergoing treatment at major school refusal treatment centers in Hiroshima Prefecture. On the whole, school

refusal in the prefecture was found to peak between 13 and 14 years of age. By age group, the main reason for school refusal in elementary school group was parent-child relationship with separation anxiety. Given additional problems such as neglect at home and complicated social situations in their schools, junior high school students were found to present diverse symptoms from introversion and self-analysis to extroversion, neglect of studies, and delinquency. Among high school students, there were more cases suffering withdrawal and schizophrenia spectrum disorders. The major task regarding treatment seems to lie in how to treat complex cases combining different problems. We summarized herein the studies we have carried out and propose a model for a network therapy system based on functional liaisons between treatment centers. With this system, a child psychiatric medical facility plays the part of a liaison center for the overall network system.

Nixon RD, Sweeney L, Erickson DB, Touyz SW. Parent-child interaction therapy: a comparison of standard and abbreviated treatments for oppositional defiant preschoolers. *J Consult Clin Psychol* 2003; 71(2):251-60.

Abstract: Families of 54 behaviorally disturbed preschool-aged children (3 to 5 years) were randomly assigned to 1 of 3 treatment conditions: standard parent-child interaction therapy (PCIT; STD); modified PCIT that used didactic videotapes, telephone consultations, and face-to-face sessions to abbreviate treatment; and a no-treatment waitlist control group (WL). Twenty-one nondisturbed preschoolers were recruited as a social validation comparison condition. Posttreatment assessment indicated significant differences in parent-reported externalizing behavior in children, and parental stress and discipline practices from both treatment groups on most measures compared with the WL group. Clinical significance testing suggested a superior effect for the STD immediately after intervention, but by 6-month follow-up, the two groups were comparable. The findings indicate that abbreviated PCIT may be of benefit for families with young conduct problem children.

Noeker M. [Factitious disorder and factitious disorder by proxy]. *Prax Kinderpsychol Kinderpsychiatr* 2004; 53(7):449-67.

Abstract: Similar to the adult patient, a child or adolescent may actively feign or produce artificial symptoms (synonymous: Munchausen syndrome). The more frequent case is that the child suffers from being an object of symptom fabrication induced by a close person caring for the child, regularly the mother (Munchausen syndrome by proxy). This review focuses on psychopathological aspects of the clinically more relevant factitious disorder by proxy. Typical behaviour and personality characteristics are presented that can be taken as clinical warning signs. Doctor-mother-interaction is affectively challenging due to

conflicting tasks imposed on the physician. Complementary to pediatric exclusion of genuine disease, psychopathological assessment is required to exclude other sources of deviant illness behaviour. Factitious disorder shares particular features (active violation of the child, false report of history, aggravated symptom presentation and increased doctor-hopping, difficulties in conforming maternal report in biomedical data) with other psychopathological entities (child abuse, simulation, dissociative disorders, somatoform disorders including hypochondria, variants of maternal overprotection and infantilization, psychosis or delusion in the mother). Criteria for differentiation are presented. Three concepts on the psychopathological etiology of factitious disorder by proxy are relevant: In some cases, it may be conceived as secondary manifestation of a primary psychopathological entity or personality disorder. Learning theory emphasises operant rewards received from vicarious sick role. Attachment theory provides possible explanations concerning the traumatic impact on the child, early sources of psychopathology in the fabricating mother and risks for intergenerational transmission of factitious disorders.

Nokes DJ, Okiro EA, Ngama M *et al.* Respiratory syncytial virus epidemiology in a birth cohort from Kilifi district, Kenya: infection during the first year of life. *J Infect Dis* 2004; 190(10):1828-32.

Abstract: We report estimates of incidence of respiratory syncytial virus (RSV) infection during the first year of life for a birth cohort from rural, coastal Kenya. A total of 338 recruits born between 21 January 2002 and 30 May 2002 were monitored for symptoms of respiratory infection by home visits and hospital referrals. Nasal washings were screened by use of immunofluorescence. From 311 child-years of observation (cyo), 133 RSV infections were found, of which 48 were lower respiratory tract infections (LRTIs) and 31 were severe LRTIs, resulting in 4 hospital admissions. There were 121 primary RSV infections (248 cyo), of which 45 were LRTIs and 30 were severe LRTIs, resulting in 4 hospital admissions; there was no association with age. RSV contributed significantly to total LRTI disease in this vaccine-target group.

Noland JS, Singer LT, Short EJ *et al.* Prenatal drug exposure and selective attention in preschoolers. *Neurotoxicol Teratol* 2005; 27(3):429-38.

Abstract: Deficits in sustained attention and impulsivity have previously been demonstrated in preschoolers prenatally exposed to cocaine. We assessed an additional component of attention, selective attention, in a large, poly-substance cocaine-exposed cohort of 4 year olds and their at-risk comparison group. Employing postpartum maternal report and biological assay, we assigned children to overlapping exposed and complementary control groups for maternal use of cocaine, alcohol, marijuana,

and cigarettes. Maternal pregnancy use of cocaine and use of cigarettes were both associated with increased commission errors, indicative of inferior selective attention. Severity of maternal use of marijuana during pregnancy was positively correlated with omission errors, suggesting impaired sustained attention. Substance exposure effects were independent of maternal postpartum psychological distress, birth mother cognitive functioning, current caregiver functioning, other substance exposures and child concurrent verbal IQ.

Nooraudah AR, Mohd Sham K, Zahari N, Fauziah K. Non-accidental fatal head injury in small children--a clinicopathological correlation. *Med J Malaysia* 2004; 59(2):160-5.

Abstract: Non-accidental head injury leading to massive intracranial trauma has been identified as a leading cause of death in small children. In a typical case, a child usually below the age of one year is violently shaken, leading to rupture of the connecting veins between the dura mater and the brain substance with variable degrees of bleeding into the subdural space resulting in increased intracranial pressure. The accompanying venous thrombosis affecting the vessels of the brain substance leads to cerebral hypoxia and cellular death. In this study conducted throughout the year 1999, all children below the age of 3 years who were admitted to Hospital Kuala Lumpur and had died due to non-accidental injuries were included. Postmortems, including histopathological studies, were conducted to determine the most likely mechanisms of the injuries. Ten cases were identified for the whole year. In 2 cases, both below one year of age, the features presented showed evidence of violent shaking of the infants. In 6 other cases whose average age was 13 (range 4-24) months, there were evidences of direct trauma and violent shaking. In the last two cases, aged 24 and 33 months respectively, there was only evidence of direct trauma on the heads without being shaken. This study shows that death due to intracranial trauma caused by shaking with or without direct impact is the most frequent cause of mortality in abused children. Death due to direct impact between the head and another object is a less frequent occurrence.

Norr KF, Crittenden KS, Lehrer EL *et al.* Maternal and infant outcomes at one year for a nurse-health advocate home visiting program serving African Americans and Mexican Americans. *Public Health Nurs* 2003; 20(3):190-203.

Abstract: This article describes the outcomes at 1 year for a randomized clinical trial of Resources, Education and Care in the Home-Futures: a program to reduce infant mortality through home visits by a team of trained community residents led by a nurse. Low-income, inner-city pregnant women who self-identified as African American or Mexican American were recruited in two university prenatal clinics in Chicago. Because African Americans and Mexican Americans

differed greatly at intake, we compared their outcomes at 12 months and then examined the effects of the intervention separately for these two groups. Participants were randomly assigned to the intervention or control group and were interviewed during the last trimester of pregnancy and at 2, 6, and 12 months after birth. The effects of the program varied by race/ethnicity. For African Americans, the program was associated with better maternal documentation of infant immunizations, more developmentally appropriate parenting expectations, and higher 12-month infant mental development scores. For Mexican Americans, the program had positive effects on maternal daily living skills and on the play materials subscale of the Home Observation for the Measurement of the Environment assessment. This study, along with previous research, suggests that home visits by a nurse-health advocate team can improve maternal and infant outcomes even for inner-city, low-income, minority families. Effective programs must be culturally sensitive, intensive, and adequately staffed and financed.

Novins DK, King M, Stone LS. Developing a plan for measuring outcomes in model systems of care for American Indian and Alaska Native children and youth. *Am Indian Alsk Native Ment Health Res* 2004; 11(2):88-98.

Abstract: The Circles of Care initiative emphasized the importance of developing an outcomes measurement plan that was consonant with the model system of care as well as community values and priorities. This analysis suggests that the Circles of Care grantees achieved this key programmatic objective, but that a major constraint was the tendency of funders, including the Substance Abuse and Mental Health Services Administration (the funder of Circles of Care), to mandate their own outcomes measurement plans. Funders are encouraged to balance their needs for commonality of measures across programs for their own evaluation purposes with the needs of service providers to utilize measures that meet their unique programmatic and community contexts.

Novins DK, LeMaster PL, Jumper Thurman P, Plested B. Describing community needs: examples from the Circles of Care initiative. *Am Indian Alsk Native Ment Health Res* 2004; 11(2):42-58.

Abstract: The assessment of community needs was one of the key foundations of the Circles of Care planning effort. Grantees identified a range of needs at the child, adolescent, family, programmatic, and community levels. This information, along with an emphasis on the

importance of each community's history and culture, served as an important guide for each program as they developed their model systems of care.

Nowinski CV, Minshew NJ, Luna B, Takarae Y, Sweeney JA. Oculomotor studies of cerebellar function in autism. *Psychiatry Res* 2005; 137(1-2):11-9. Abstract: Histopathological, neuroimaging and genetic findings indicate cerebellar abnormalities in autism, but the extent of neurophysiological dysfunction associated with those findings has not been systematically examined. Suppression of intrusive saccades (square wave jerks) and the ability to sustain eccentric gaze, two phenomena requiring intact cerebellar function, were examined in 52 high-functioning individuals with autism and 52 age- and IQ-matched healthy subjects during visual fixation of static central and peripheral targets. Rates of intrusive saccades were not increased in autism during visual fixation, and foveopetal ocular drift was also not increased when subjects held an eccentric gaze. The absence of gross disturbances of visual fixation associated with cerebellar disease in individuals with autism, such as increased square wave jerk rates and foveopetal drift when holding eccentric gaze, indicates that the functional integrity of cerebellar--brainstem networks devoted to oculomotor control is preserved in autism despite reported anatomic variations. However, increased amplitude of intrusive saccades and reduced latency of target refixation after intrusive saccades were observed in individuals with autism, especially when subjects maintained fixation of remembered target locations without sensory guidance. The atypical metrics of intrusive saccades that were observed may be attributable to faulty functional connectivity in cortico-cerebellar networks.

Nullis-Kapp C. The knowledge is there to achieve development goals, but is the will? *Bull World Health Organ* 2004; 82(10):804-6.

Nunn PE. A study examining the health perceptions and parenting stressors of parenting African-American grandparents. *ABNF J* 2002; 13(5):99-102. Abstract: The objectives of this study of African-American, parenting grandparents were to examine the antecedents to grandparent parenting, the grandparents' perception of their health status, and their assessment of parenting stress. Thirty-one subjects completed a demographic questionnaire, two questions from the Short form-36-Health Survey, and the Parenting Stress Index (PSI). Results indicated that the grandparents parented minor grandchildren because of biological

parent neglect/abuse, abandonment, mental illness, substance abuse, teen mother, or death of a parent. While most grandparents considered their health to be satisfactory, the grandparents, ages thirty to sixty reported a greater number of health concerns. The PSI identified life stress greater than parenting stress. In conclusion, additional research is needed to identify life stresses that add to the parenting burden, and grandparents' needs to continue parenting.

Nwomeh BC, Waller AL, Caniano DA, Kelleher KJ. Informed consent for emergency surgery in infants and children. *J Pediatr Surg* 2005; 40(8):1320-5. Abstract: The informed consent process for emergency surgery in children poses a challenge for pediatric surgeons because the child and his/her surrogates (usually parents) must make medical decisions in a relatively short period. The unique circumstances of a surgical emergency create potential barriers to achieving the central goals of the informed consent process, respect for patient autonomy and beneficence. The purpose of this review is to provide a practical guide for pediatric surgeons on the informed consent process as it applies to emergency surgery in pediatric patients. We will also discuss innovative methods of preoperative education that can be adopted in the emergency setting and highlight areas in which further research might help to improve this important aspect of surgical care.

Nyambedha EO, Wandibba S, Aagaard-Hansen J. Policy implications of the inadequate support systems for orphans in western Kenya. *Health Policy* 2001; 58(1):83-96.

Abstract: This paper describes the support systems available for orphans in a rural Luo community in Nyang'oma sub-location in Bondo District of Western Kenya. Qualitative data were collected through in-depth interviews with orphaned children and their caretakers as well as key informants, and through focus group discussions with orphaned children, widows and community elders. Quantitative data were obtained by questionnaires administered to 100 caretakers of orphaned children. The most serious problem was inability of the orphan households to afford school fees, although lack of food, medicare and clothing were also prominent. The traditional, kinship-based support systems made a major contribution to catering for the orphans though the resources were far from enough. Various community-based groups in the area did not contribute significantly. The problem is getting desperate due to a combination of an exponentially

increasing prevalence of orphans, poor socio-economic conditions and decline of the traditional support systems. For health planners and policy makers there are two major concerns. In the short term, a big and rapidly growing group of children are without adequate access to health services, while in the long term, the negative consequences for (in particular the girl) orphans' schooling pose a serious threat to the health of their future children. Based on the study findings, two recommendations are made: that the responsible parties address the issue of education for orphans rapidly and sufficiently and with due consideration of their food security and medicare; and that potential community resources such as kinship networks and community groups are mobilised in order to assist in achieving the goal.

O'Brien D. Borderline viability resuscitation cases. *Med Etika Bioet* 2002; 9(3-4):6-10.  
Notes: GENERAL NOTE: KIE: 11 refs.  
GENERAL NOTE: KIE: KIE Bib: allowing to die/infants; allowing to die/religious aspects; resuscitation orders  
Abstract: Decisions on whether to resuscitate severely premature infants are especially difficult in "borderline viability" cases--those where the probability of survival is slim, and where, if survival is possible, multiple comorbidities and severe disabilities are likely. The 2000 International Guidelines on Cardiopulmonary Resuscitation are comprehensive, yet leave open some of the more difficult ethical questions that must be addressed by decision-makers. This paper recommends evidence-based, clinical ethical guidelines for neonatal resuscitation, drawing on one large Catholic health system's approach, arguing from the perspective of the Catholic moral tradition and the Ethical and Religious Directives for Catholic Health Care Services (the ERD are policy for all of Catholic health care in the U.S.). The paper presumes that there is an inherent dignity of the human person to be respected and protected regardless of the nature of the person's health problem or social status. But it also presumes and argues that treatments can be justified only by a proportionate benefit to the patient. In maintaining a holistic view of the human person, two extremes are avoided: a "vitalistic" approach where life is preserved at all costs; and the "easy" alternative of euthanasia. Several principles of medicine, theology, ethics and Anglo-American common law are applied to three categories of preterm infants, each of which calls for a different basic response: Category I - infants with a confirmed gestational age of < 23-0/7 weeks; Category II - infants with a confirmed gestational age between 23-0/7 and 25-0/7 weeks; and Category III - infants with a gestational age > 25-0/7 weeks. Studies show that survival rates and outcomes vary dramatically for these three groups, even with the availability of the latest technologies.

O'Brien SM. Staying alive: a client with chronic mental

illness in an environment of domestic violence. *Holist Nurs Pract* 2002; 16(3):16-23.  
Abstract: This case study of a young, African American mother with chronic mental illness demonstrates the impact of domestic violence on a vulnerable population. The client was economically disadvantaged, socially isolated, stigmatized, and victimized by repeated abuse from her live-in male partner of 7 years. With this overlay of violence in the home, the client experienced a downward trajectory in health, self-esteem, economic status, personal freedom, social relationships, and legal standing. Using a public health model in the context of an urban nursing center, an advanced practice nurse provided case management and outreach services for the client.

O'Connor LA, Morgenstern J, Gibson F, Nakashian M. "Nothing about me without me": leading the way to collaborative relationships with families. *Child Welfare* 2005; 84(2):153-70.  
Abstract: This article discusses the National Center on Addiction and Substance Abuse's CASA Safe Haven, an evidence-based, community-driven intervention program for children and families in child welfare whose lives have been adversely affected by substance abuse, and for staff in the agencies that work with them. CASA Safe Haven builds collaborative relationships that feature a blend of multidisciplinary teams that share responsibility for helping families; family group conferencing, in which families are equal and welcome participants in designing and driving a service plan; and the influence of family court to hold families and service providers accountable for progress. CASA Safe Haven is a framework for collaboration.

O'Donnell L, Stueve A, Agronick G, Wilson-Simmons R, Duran R, Jeanbaptiste V. Saving Sex for Later: an evaluation of a parent education intervention. *Perspect Sex Reprod Health* 2005; 37(4):166-73.  
Abstract: CONTEXT: Initiation of sexual intercourse prior to high school is prevalent among inner-city black and Hispanic youths, and has multiple negative health and social consequences. A promising strategy for addressing early adolescent sexual activity is parent education that addresses normal pubertal changes and the challenges of becoming a teenager. METHODS: A 2003-2005 randomized trial to test the effectiveness of Saving Sex for Later, a parent education program presented on three audio CDs, enrolled 846 families with fifth- and sixth-grade students in seven New York City schools. Parent and youth surveys were conducted

at baseline and three months postintervention. Multivariate logistic and linear regression analyses were performed to assess relationships between youth and parent outcomes and treatment condition. RESULTS: At follow-up, parents in the intervention group were significantly more likely than controls to score high on indexes of communication with children about targeted risk behaviors, self-efficacy to discuss pubertal development and sexuality, and perceived influence over youths' behaviors (odds ratios, 1.9-2.5). Youths in the intervention condition were more likely than controls to report high family support, and reported more family rules and fewer behavioral risks. Family support and rules partially mediate the relationship between treatment condition and behavioral risks. CONCLUSION: Saving Sex for Later is a promising intervention for promoting youths' sexual abstinence. The intervention may also be effective in enhancing positive parenting practices among parents who are typically difficult to reach because of economic hardship, full schedules and complicated lives.

O'Doriso MS, Hauger M, O'Doriso TM. Age-dependent levels of plasma neuropeptides in normal children. *Regul Pept* 2002; 109(1-3):189-92. Abstract: Several neuropeptides are secreted in high amounts in pediatric tumors such as neuroblastoma and have been used as markers of residual or recurrent disease. Plasma levels of neuropeptides might be expected to change during development, but have not been determined in normal children. We have obtained fresh plasma from cord blood of six full-term infants and from peripheral blood in 41 healthy children, ages 1 month to 21 years. Levels of six neuropeptides, vasoactive intestinal peptide (VIP), somatostatin, gastrin releasing peptide (GRP), substance P, pancreastatin and neuropeptide Y (NPY) were measured by radioimmunoassay along with insulin-like growth factor-1 (IGF-1) whose plasma levels are known to vary during development. A child with neuroblastoma was treated with the somatostatin analogue, octreotide, and the effect on plasma neuropeptides quantified. Octreotide doses of 2-3 microg/kg daily resulted in a 40-60% decrease in plasma levels of IGF-1, pancreastatin and GRP. These results are the first publication of plasma neuropeptide levels in normal children.

O'Leary CM. Fetal alcohol syndrome: diagnosis, epidemiology, and developmental outcomes. *J Paediatr Child Health* 2004; 40(1-2):2-7. Abstract: In Australia the issue of fetal alcohol syndrome (FAS) has not been the subject of policy

development or of extensive research. There is a lack of knowledge, both in the general community and by health professionals, of the nature of the risks associated with heavy alcohol consumption during pregnancy and the factors that increase this risk. This paper reviews the literature surrounding FAS with the aim of providing the reader an understanding of the diagnostic features and epidemiology of FAS and of the developmental sequelae associated with this syndrome.

O'Leary D, Jyringi D, Sedler M. Childhood conduct problems, stages of Alzheimer's disease, and physical aggression against caregivers. *Int J Geriatr Psychiatry* 2005; 20(5):401-5.

Abstract: OBJECTIVE: To assess the prevalence of physical aggression against caregivers by Alzheimer's patients. METHOD: One hundred and ninety-eight individuals with dementia, primarily Alzheimer's disease (AD) were evaluated with the Cohen-Mansfield Agitation Inventory, the Mini Mental Status Examination, two measures of Activities of Daily Living, portions of the Conflict Tactics Scale to measure physical aggression against partner, questions about conduct problems during childhood/adolescence of the patients, and chart records of delusion and paranoia. RESULTS: 25% of the patients engaged in physical aggression against their caregivers in the past year, and 33% of the patients engaged in some act of physical aggression against any individual in the past two weeks. Physical aggression against a caregiver was more likely in the middle (34%) than the early stage of AD (4%). Physical aggression against a partner and agitation were more likely if the patient had a history of symptoms of conduct disorder. Delusions and paranoia were both associated with general physical aggression and general verbal aggression but not physical aggression against a caretaker. CONCLUSIONS: 25% of Alzheimer's disease and Multi-Infarct dementia patients engaged in acts of physical aggression against their caregivers. The rate of aggression seen in this clinical sample was much higher than the rate of physical aggression in a community sample of the elderly.

O'Leary SG, Vidair HB. Marital adjustment, child-rearing disagreements, and overreactive parenting: predicting child behavior problems. *J Fam Psychol* 2005; 19(2):208-16.

Abstract: Using structural equation modeling, the authors evaluated the hypothesis that the relation between marital adjustment and children's behavior problems is mediated by child-rearing disagreements, whose effects are mediated by parents' overreactive discipline. In a community sample, fully or partially mediated models of internalizing and externalizing behavior problems of 3- to 7-year-old boys (N = 99) and girls (N = 104) were supported for mothers and fathers in 7 of 8 cases. Child-rearing disagreements always mediated the relation of marital adjustment and

- child behavior problems, and overreactive discipline was a final mediator in 3 cases. More variance was accounted for in mothers' than fathers' ratings. For mothers' ratings, the most variance was accounted for in boys' externalizing and girls' internalizing behavior problems.

- O'Shaughnessy RJ. Violent adolescent sexual offenders. *Child Adolesc Psychiatr Clin N Am* 2002; 11(4):749-65.  
 Abstract: The past 20 years have brought a significant increase in the general knowledge about adolescent offenders and sexual offenders and the potential harm that they cause to victims. Currently, however, we are left with perhaps more questions than answers in several important areas. We have concluded that there is no single cause or etiologic agent common to all sexual offenders. Sexual offenders are by nature a complex and a heterogeneous group, and sexual offending is likely caused by multiple causation and interactive factors. Awareness has spread as to the necessity of providing appropriate assessment and treatment facilities for adolescents. The limited outcome studies indicate a lower recidivism rate for adolescent offenders than adult offenders. This may reflect a better prognosis for adolescent offenders who have not had years of reinforcement of deviant sexual arousal patterns and whose personality traits are more malleable than those of adult offenders. Further research is needed in the area of subclassification of sexual offenders, controlled treatment studies, and prospective longitudinal studies to determine more accurate risk assessment.

- Ochsner AK, Alexander JL, Davis A. Increasing awareness of asthma and asthma resources in communities on the southwest border. *J Am Acad Nurse Pract* 2002; 14(5):225-30, 232, 234.  
 Abstract: PURPOSE: To provide outpatient asthma education for children and families along the southwest border of the U.S. and to study the effectiveness of a southwest border hospital's in-house asthma educational program. DATA SOURCES: (1) "Increasing the Knowledge Base of Asthmatics and Their Families through Asthma Clubs along the Southwest Border." (2) American Lung Association. (3) National Institutes of Health, National Heart, Lung and Blood Institute. (4) Referrals from a southwest border hospital. CONCLUSIONS: Only two of 23 patients referred for asthma follow-up were readmitted to hospital and/or emergency care during the following year. Large group teaching pretest-posttest score means for 3,429 fourth and fifth grade students revealed a 23% increase in asthma knowledge. Small follow-up groups of students received in-depth asthma education. IMPLICATIONS FOR PRACTICE: Effectiveness of hospital inpatient asthma education combined with outpatient family follow-up was supported. An additional finding was that southwest border families are more receptive to visits arranged with a school nurse in their children's school than to home visits from primary care clinic nurses.
- Oermann MH, Lowery NF, Thornley J. Evaluation of Web sites on management of pain in children. *Pain Manag Nurs* 2003; 4(3):99-105.  
 Abstract: Increasingly, consumers access the Internet for information about their health problems and treatments and to learn more about their health care. Although Web sites can be valuable resources, the information may not be accurate or current. The purpose of this project was to evaluate the quality of Web sites for parents on the management of children's pain. The Health Information Technology Institute criteria were used to evaluate 40 Web sites identified from two search engines: MSN and Google. After the evaluation process was completed, the readability of the sites was determined. Of the 40 sites, 29 (72.5%) provided useful information for parents searching to educate themselves about pain management. Other sites advertised the pain management services of their facility or were not relevant for patient education. The reading levels of the Web sites ranged from grade 7.7 to 12; the mean reading grade level of the 40 sites was 10.8, too high for many consumers. This article discusses the role of the nurse in evaluating health Web sites and teaching patients how best to use the Web for their health information.
- Oh KJ, Shin YJ, Moon KJ, Hudson JL, Rapee RM. Child-rearing practices and psychological disorders in children: cross-cultural comparison of Korea and Australia. *Yonsei Med J* 2002; 43(4):411-9.  
 Abstract: The present study was designed to explore cultural differences in the relationship between parenting behaviors and psychological adjustment of the child. Mother-son interaction behaviors of 37 Korean boys (11 with Anxiety Disorder, 10 with Externalizing Disorders and 16 Non-clinical boys) and 54 Australian boys (20 with Anxiety Disorder, 17 with Externalizing Disorders and 17 Non-clinical boys)

between the ages of 7 and 15 were compared in terms of parental negativity and involvement. The results indicated that Korean mothers displayed more overall negativity and lower overall involvement than Australian mothers. Furthermore, anxiety diagnosis was associated with low maternal involvement in the Korean subjects, while in the Australian subjects, high maternal involvement was associated with clinical status in the child.

Ohan JL, Johnston C. Gender appropriateness of symptom criteria for attention-deficit/hyperactivity disorder, oppositional-defiant disorder, and conduct disorder. *Child Psychiatry Hum Dev* 2005; 35(4):359-81. Abstract: We examined the gender appropriateness of the DSM-IV symptoms of attention-deficit/hyperactivity disorder (ADHD), oppositional defiant disorder (ODD), and conduct disorder (CD). In Study 1, 100 mothers (35 of children with and 65 of children without ADHD) rated how gender-typical and problematic they saw DSM-IV symptoms of ADHD, ODD, and CD; feminine descriptions of ADHD, ODD, and CD behaviors that we created; and relationally and overtly aggressive behaviors. Mothers rated the DSM-IV symptoms and overt aggression as boy-descriptive, and the feminine items that we created and relational aggression as girl-descriptive. Mothers saw the feminine items as less problematic than the masculine items. In Study 2, for 80 girls (40 with and 40 without ADHD), mothers' ratings on the feminine items were related to the corresponding DSM-IV symptoms, and to general psychopathology and impairment. Most correlations were significant and support the construct validity of the feminine items.

Ohanaka EC. Discharge against medical advice. *Trop Doct* 2002; 32(3):149-51. Abstract: An audit of surgical patients who requested discharge against medical advice over a 5 year period (July 1996-July 2001) at the University of Benin Teaching Hospital showed that 78 patients (66 males and 12 females) were involved. The age range was 3 days to 85 years (mean 37.86 years). The 21-40 age group was the most involved. Trauma in general accounted for the most common clinical condition that caused a patient to discharge against medical advice (64 or 82%), while fracture involving the long bones was the most common condition (37 or 47.4%). The plausible reasons for this practice have been outlined including measures that may help to reduce discharge against medical advice in a developing country.

Ohannessian CM, Hesselbrock VM, Kramer J *et al.* The relationship between parental alcoholism and adolescent psychopathology: a systematic examination of parental comorbid psychopathology. *J Abnorm Child Psychol* 2004; 32(5):519-33. Abstract: The relationship between parental alcohol dependence (with and without comorbid

psychopathology) and adolescent psychopathology was examined in a sample of 665 13-17 year-old adolescents and their parents. Results indicated that adolescents who had parents diagnosed with alcohol dependence only did not significantly differ from adolescents who had parents with no psychopathology in regard to any of the measures of psychological symptomatology (substance use, conduct disorder, and depression) or clinical diagnoses (alcohol dependence, marijuana dependence, conduct disorder, or depression) assessed. In contrast, adolescents who had parents diagnosed with alcohol dependence and either comorbid drug dependence or depression were more likely to exhibit higher levels of psychological symptomatology. In addition, adolescents who had parents diagnosed with alcohol dependence, depression, and drug dependence were most likely to exhibit psychological problems. These findings underscore the importance of considering parental comorbid psychopathology when examining the relationship between parental alcoholism and offspring adjustment.

Ohnishi T, Moriguchi Y, Matsuda H *et al.* The neural network for the mirror system and mentalizing in normally developed children: an fMRI study. *Neuroreport* 2004; 15(9):1483-7. Abstract: We performed fMRI measurements in normal children to clarify which cortical areas are commonly involved in the mirror system (MS) and mentalizing, which areas are specific for mentalizing, and whether children have the same neural networks for MS and mentalizing as adults. Normal children had the same neural networks for the MS and mentalizing as adults. Common activations were found in the superior temporal sulcus and the fusiform gyri, whereas mentalizing specific activation was found in the medial prefrontal, temporal pole and the inferior parietal cortices. We suggest that mentalizing might evolve from a capacity to detect the motion of agents and to infer intentions. Further, mentalizing might require self-perspectives.

Ojeda SR, Heger S. New thoughts on female precocious puberty. *J Pediatr Endocrinol Metab* 2001; 14(3):245-56.

Abstract: Much effort has been devoted in recent years to unravel the neuroendocrine mechanisms responsible for the initiation of mammalian puberty. The concept that has emerged is that puberty results from the unfolding of a centrally originated process involving the concerted influence of neuronal systems that utilize excitatory and inhibitory amino acids as transmitters and astroglial networks that produce growth factors able to affect LHRH secretion. We discuss the idea that an isolated alteration of each of these components may result in the precocious activation of pulsatile LHRH release, and thus lead to idiopathic sexual precocity. According to this notion, such a premature activation of LHRH neuronal function would be neither

associated with structural damage of the neuroendocrine brain system, nor related to a generalized activation of the neuronal-glia mechanisms underlying the onset of puberty. On the contrary, localized activation of discrete cellular subsets functionally connected to LHRH neurons would suffice to promote an increase in LHRH release of sufficient magnitude and duration to initiate the pubertal process.

Okabayashi H, Liang J, Krause N, Akiyama H, Sugisawa H.

Mental health among older adults in Japan: do sources of social support and negative interaction make a difference? *Soc Sci Med* 2004; 59(11):2259-70. Abstract: This study addresses the question of whether social support and interpersonal strain from different sources (i.e., spouse, children, and other relatives and friends) have differential impact on mental health. Data for this research came from a national probability sample of 2200 persons aged 60 and over in Japan. Structural equation models were evaluated within the context of two types of social networks: (a) persons who had a spouse and children (n=1299), and (b) those with children only (n=677). Between these two networks, the links among social support, negative relations, and mental health were contrasted. The effects of various sources of social support and negative interactions on mental health vary depending on the specific dimension of mental health as well as the nature of social networks. Among older Japanese who are married with children, social support from spouse has a greater association with positive well-being than social support from children and others. However, cognitive functioning is uncorrelated with all sources of positive and negative social exchanges. In contrast, among those without a spouse, only greater support from children is significantly correlated with higher positive well-being, less distress, and less cognitive impairment.

Okoromah CN, Egri-Qkwaji MT. Profile of and control measures for paediatric discharges against medical advice. *Niger Postgrad Med J* 2004; 11(1):21-5. Abstract: BACKGROUND: Children are minors in health decision-making and discharges against medical advice (DAMA) may portend adverse health, social and psychological consequences. This study was aimed at ascertaining the prevalence rate and the determining clinical, sociodemographic factors as well as caregivers' perceptions associated with paediatric DAMA with the view of proffering possible control measures. DESIGN: Pre-tested administered questionnaires were used to collect relevant data

prospectively (March 2000- March 2002) from consecutive patients undertaking DAMA. RESULTS: Prevalence rate of DAMA was 1.2%, comprising 202 of 16,440 discharges, of which 95 (47.0%) were neonates. Neonatal jaundice, gross congenital anomalies and severe birth asphyxia among neonates, and bronchopneumonia, gastroenteritis, malaria and malignancies among infant and older children, were the commonest diagnoses. Twenty (9.9%) cases were critically ill and 53(26.2%) were partially improved at discharge. Perceived improvement of illness, preference for outpatient care, financial constraints, high cost of hospital services, dissatisfaction and disagreements with care, were the commonest reasons for DAMA. CONCLUSION: DAMA is of multifactorial aetiology, involving clinically heterogeneous patients who may be critically ill or partially recovered. Socioeconomic, quality and cost of health care are implicated. This study recommends some control measures.

Olauson A. The Agrenska centre: a socioeconomic case study of rare diseases. *Pharmacoeconomics* 2002; 20 Suppl 3:73-5.

Abstract: The Agrenska Centre in Gothenburg, Sweden, provides support services to children with disabilities and their families; these services include a unique programme of family activities, respite services, education, information projects, and research. Participants in their programmes have noted how their experiences at the Agrenska Centre differed from their experiences with the healthcare system in other parts of Sweden. The Department of Economics at the University of Gothenburg conducted a study to evaluate whether the benefits of the Agrenska approach might also extend to healthcare savings. There was, in fact, nearly a three-fold decrease in direct and indirect healthcare costs for families using the Agrenska Centre versus those utilising only routine support services. The implication is that society and governments can ill afford not to seek new ways to organise support networks for patients with rare disorders.

Olds DL, Robinson J, O'Brien R *et al.* Home visiting by paraprofessionals and by nurses: a randomized, controlled trial. *Pediatrics* 2002; 110(3):486-96. Abstract: OBJECTIVE: To examine the effectiveness of home visiting by paraprofessionals and by nurses as separate means of improving maternal and child health when both types of visitors are trained in a program model that has demonstrated effectiveness when delivered by nurses. METHODS: A randomized, controlled trial was conducted in public- and private-

care settings in Denver, Colorado. One thousand one hundred seventy-eight consecutive pregnant women with no previous live births who were eligible for Medicaid or who had no private health insurance were invited to participate. Seven hundred thirty-five women were randomized to control, paraprofessional, or nurse conditions. Nurses completed an average of 6.5 home visits during pregnancy and 21 visits from birth to the children's second birthdays. Paraprofessionals completed an average of 6.3 home visits during pregnancy and 16 visits from birth to the children's second birthdays. The main outcomes consisted of changes in women's urine cotinine over the course of pregnancy; women's use of ancillary services during pregnancy; subsequent pregnancies and births, educational achievement, workforce participation, and use of welfare; mother-infant responsive interaction; families' home environments; infants' emotional vulnerability in response to fear stimuli and low emotional vitality in response to joy and anger stimuli; and children's language and mental development, temperament, and behavioral problems. **RESULTS:** Paraprofessional-visited mother-child pairs in which the mother had low psychological resources interacted with one another more responsively than their control-group counterparts (99.45 vs 97.54 standard score points). There were no other statistically significant paraprofessional effects. In contrast to their control-group counterparts, nurse-visited smokers had greater reductions in cotinine levels from intake to the end of pregnancy (259.0 vs 12.32 ng/mL); by the study child's second birthday, women visited by nurses had fewer subsequent pregnancies (29% vs 41%) and births (12% vs 19%); they delayed subsequent pregnancies for longer intervals; and during the second year after the birth of their first child, they worked more than women in the control group (6.83 vs 5.65 months). Nurse-visited mother-child pairs interacted with one another more responsively than those in the control group (100.31 vs 98.99 standard score points). At 6 months of age, nurse-visited infants, in contrast to their control-group counterparts, were less likely to exhibit emotional vulnerability in response to fear stimuli (16% vs 25%) and nurse-visited infants born to women with low psychological resources were less likely to exhibit low emotional vitality in response to joy and anger stimuli (24% vs 40% and 13% vs 33%). At 21 months, nurse-visited children born to women with low psychological resources were less likely to exhibit language delays (7% vs 18%); and at 24 months, they exhibited superior mental development (90.18 vs 86.20 Mental Development Index scores) than their control-group counterparts. There were no statistically significant program effects for the nurses on women's use of ancillary prenatal services, educational achievement, use of welfare, or their children's temperament or behavior problems. For most outcomes on which either visitor produced significant effects, the paraprofessionals typically had effects that were about half the size of those produced by nurses.

**CONCLUSIONS:** When trained in a model program of prenatal and infancy home visiting, paraprofessionals produced small effects that rarely achieved statistical or clinical significance; the absence of statistical significance for some outcomes is probably attributable to limited statistical power to detect small effects. Nurses produced significant effects on a wide range of maternal and child outcomes.

Oleke C, Blystad A, Rekdal OB. "When the obvious brother is not there": political and cultural contexts of the orphan challenge in northern Uganda. *Soc Sci Med* 2005; 61(12):2628-38.

**Abstract:** It is estimated that two million of Uganda's children today are orphaned primarily due to AIDS. While recognising the immense impact of HIV/AIDS on the present orphan problem, this article calls for a broader historic and cultural contextualisation to reach an understanding of the vastness of the orphan challenge. The study on which the article is based was carried out among the Langi in Lira District, northern Uganda, with a prime focus on the situation of orphans within the extended family system. The data were collected through ethnographic fieldwork (8 months); in-depth interviews with community leaders (21), heads of households (45) and orphans (35); through focus group discussions (5) with adult men and women caring for orphans, community leaders and with orphans; and also through documentary review. A survey was conducted in 402 households. The findings reveal a transition over the past 30 years from a situation dominated by 'purposeful' voluntary exchange of non-orphaned children to one dominated by 'crisis fostering' of orphans. Sixty-three percent of the households caring for orphans were found to be no longer headed by resourceful paternal kin in a manner deemed culturally appropriate by the patrilineal Langi society, but rather by marginalised widows, grandmothers or other single women receiving little support from the paternal clan. This transition is partly linked to an abrupt discontinuation of the Langi 'widow inheritance' (laku) practice. It is argued that the consequential transformations in fostering practices in northern Uganda must be historically situated through a focus on the effects of armed conflicts and uprooting of the local pastoral and cotton-based economy, which have occurred since the late 1970s. These processes jointly produced dramatic economic marginalisation with highly disturbing consequences for orphans and their caretakers.

Olesen PJ, Nagy Z, Westerberg H, Klingberg T. Combined analysis of DTI and fMRI data reveals a joint maturation of white and grey matter in a fronto-parietal network. *Brain Res Cogn Brain Res* 2003; 18(1):48-57. **Abstract:** The aim of this study was to explore whether there are networks of regions where maturation of white matter and changes in brain activity show similar developmental trends during childhood. In a previous study, we showed that during childhood, grey matter

activity increases in frontal and parietal regions. We hypothesized that this would be mediated by maturation of white matter. Twenty-three healthy children aged 8-18 years were investigated. Brain activity was measured using the blood oxygen level-dependent (BOLD) contrast with functional magnetic resonance imaging (fMRI) during performance of a working memory (WM) task. White matter microstructure was investigated using diffusion tensor imaging (DTI). Based on the DTI data, we calculated fractional anisotropy (FA), an indicator of myelination and axon thickness. Prior to scanning, WM score was evaluated. WM score correlated independently with FA values and BOLD response in several regions. FA values and BOLD response were extracted for each subject from the peak voxels of these regions. The FA values were used as covariates in an additional BOLD analysis to find brain regions where FA values and BOLD response correlated. Conversely, the BOLD response values were used as covariates in an additional FA analysis. In several cortical and sub-cortical regions, there were positive correlations between maturation of white matter and increased brain activity. Specifically, and consistent with our hypothesis, we found that FA values in fronto-parietal white matter correlated with BOLD response in closely located grey matter in the superior frontal sulcus and inferior parietal lobe, areas that could form a functional network underlying working memory function.

Olivan-Gonzalvo G. [Prevalence of hepatitis B, hepatitis C, HIV and latent tuberculosis infection and syphilis in a population of immigrant children at high social risk]. *Enferm Infecc Microbiol Clin* 2004; 22(4):250.

Oliveira RG, Marcon SS. [Infantile and juvenile sexual exploration: causes, consequences and relevant aspects for health professionals]. *Rev Gaucha Enferm* 2005; 26(3):345-57.

Abstract: This article brings a literature revision about the infantile and juvenile sexual exploration. It approaches the subject of sexual exploration in the national context by adopting, as crossed theme, different forms of violence, particularly the gender kind. It presents the causes and consequences of this kind of violence for the individuals' health. From reports on some experiences, it points out and discusses relevant aspects of the performance of health professionals when facing the problem.

Oliver-Vazquez M. [The ethics of public health]. *P R Health Sci J* 2003; 22(1):21-2.

Olson PM, Pacheco MR. Bipolar disorder in school-age children. *J Sch Nurs* 2005; 21(3):152-7.

Abstract: This article examines the individual components of bipolar disorder in children and the behaviors that can escalate as a result of misdiagnosis and treatment. The brain/behavior relationship in bipolar disorders can be affected by genetics, developmental failure, or environmental influences, which can cause an onset of dramatic mood swings and dysfunctional behavior. School is often the site where mental health disorders are observed when comparing behaviors with other children. Assessing the emotional, academic, and health needs of a student with a bipolar disorder is a critical step in designing effective interventions and school accommodations. Without appropriate medical, psychological, pharmaceutical, and academic interventions, a child is at risk for uncontrolled mania, depression, substance abuse, or suicide. The school nurse is part of the multidisciplinary team and plays a key role in facilitating case management to potentially reverse this possible negative trajectory. Successful case management provides children with bipolar disorder the opportunity to reach their academic potential.

Olson SL, Ceballo R, Park C. Early problem behavior among children from low-income, mother-headed families: a multiple risk perspective. *J Clin Child Adolesc Psychol* 2002; 31(4):419-30.

Abstract: Examined proximal and contextual factors most strongly related to externalizing behavior among young children growing up in low-income, mother-headed families. Participants were 50 low-income single mothers and their preschool-age children who were visited twice in the home setting. Measures of proximal (low levels of supportive parenting, high levels of punitive disciplinary practices, low levels of maternal emotional well-being) and contextual (low maternal support, high levels of family stress) risk were assessed in relation to maternal reports of child externalizing behavior and an index of negative child behavior during a clean-up task. Child defiance during the clean-up task was highly associated with punitive maternal control in the same situation but had no other direct correlates. However, multiple risk factors representing both proximal and contextual variables were associated with variations in children's behavior problem scores. Mothers of children with high behavior problem scores reported lower feelings of self-efficacy in handling child care and emotional stressors, more frequent use of punitive child disciplinary practices, and lower feelings of satisfaction with the quality of their supportive resources than others. Maternal self-evaluations of coping efficacy mediated the relation between perceived support and child behavior problems, suggesting that constructs of personal control are important to represent in future studies of highly stressed parents.

Omar HA. Child and adolescent prostitution. *J Pediatr Adolesc Gynecol* 2002; 15(5):329-30.

Omer H. Helping parents deal with children's acute disciplinary problems without escalation: the principle of nonviolent resistance. *Fam Process* 2001; 40(1):53-66.

Abstract: There are two kinds of escalation between parents and children with acute discipline problems: (a) complementary escalation, in which parental giving-in leads to a progressive increase in the child's demands, and (b) reciprocal escalation, in which hostility begets hostility. Extant programs for helping parents deal with children with such problems focus mainly on one kind of escalation to the neglect of the other. The systematic use of Gandhi's principle of "nonviolent resistance" allows for a parental attitude that counters both kinds of escalation. An intervention is described, which allows parents to put this principle into practice.

Omigbodun OO. Psychosocial issues in a child and adolescent psychiatric clinic population in Nigeria. *Soc Psychiatry Psychiatr Epidemiol* 2004; 39(8):667-72. Abstract: **BACKGROUND:** Psychosocial issues and interventions play a very important role in the aetiology, course and prognosis of several child psychiatric disorders. Psychosocial problems in a child and adolescent psychiatric clinic population in Nigeria were documented as a preliminary step towards the planning and development of this new facility. **METHODS:** A standardised assessment procedure was integrated into the routine at the clinic when services commenced. Psychosocial stressors and life events were measured using the interview method so that in-depth information could be obtained. **RESULTS:** Over the 3-year period of study, 79 (62.2%) of the 127 new referrals to the clinic had significant psychosocial stressors in the year preceding presentation. Problems with primary support, such as separation from parents to live with relatives, disruption of the family, abandonment by mother, psychiatric illness in a parent and sexual/physical abuse, occurred in 50 (39.4%) of the subjects. Problems with social environment occurred in 11 (8.7%), 39 (30.7%) had educational problems, 5 (3.9%) had economic problems and 15 (11.8%) of the children had "other" psychosocial stressors. Significantly more children and adolescents with disruptive behaviour disorders and disorders like enuresis, separation anxiety and suicidal behaviour had psychosocial stressors when compared to children with psychotic conditions, autistic disorder and epilepsy ( $\chi^2 = 9.6$ ;  $p = 0.048$ ). **CONCLUSIONS:** The importance of the psychosocial diagnostic dimension in routine practice is illustrated in this study. Some psychosocial factors identified are cultural practices. The effects of these practices on child mental health require further study.

Ong T, Hodgkins P, Marsh C, Taylor D. Blinding keratoconjunctivitis and child abuse. *Am J Ophthalmol* 2005; 139(1):190-1. Abstract: **PURPOSE:** To report an unusual, blinding inflicted eye injury in young children. **DESIGN:**

Observational case report. **METHODS:** Retrospective study in an institutional clinical practice of two families in whom the probands had inferior half keratoconjunctivitis and additional signs of child abuse. **RESULTS:** Two unrelated infants presented with bilateral, asymmetrical, external eye disease affecting the lower half of the cornea and conjunctiva. One eye had perforated. All eyes recovered quickly while the patients were in the hospital with no specific treatment. There were other signs of child abuse detected by further studies on the patients, and in one case, the younger sibling was the subject of severely damaging physical abuse. **CONCLUSIONS:** Inflicted corneal injuries are nonspecific, and unexplained keratoconjunctivitis, especially in the lower half of the conjunctiva and cornea in infants should alert the clinician to the possibility child abuse, but, by itself cannot be taken as being pathognomonic of abuse.

Onyskiw JE. Health and use of health services of children exposed to violence in their families. *Can J Public Health* 2002; 93(6):416-20. Abstract: **OBJECTIVE:** To obtain baseline data on the health status and use of health services of children exposed to violence in their families. **METHOD:** The study used data from the first cycle of the National Longitudinal Survey of Children and Youth (1994/95). According to parental reports, 8.6% of children ( $n = 1,648$ ; representing 329,657 children) aged 2 to 11 years witnessed some violence in their families. They were compared to children who were reported to have never witnessed any violence at home. **FINDINGS:** Children exposed to domestic violence had lower health status and more conditions or health problems which limited their participation in normal age-related activities than children in non-violent families. Despite this, they had no more contacts with family practitioners in the previous year and even fewer contacts with pediatricians than comparison children. They did, however, have more contacts with "other medical doctors," public health nurses, child welfare workers, and other therapists than comparison children. In addition, more child witnesses regularly used prescription medication than children not exposed to violence at home. **CONCLUSION:** These baseline findings suggest that exposure to domestic violence has an adverse impact on children's health and use of health services. As future cycles become available, these children will be followed to determine the long-term impact on these outcomes.

Oona M, Kalda R, Lember M, Maaros HI. Family doctors' involvement with families in Estonia. *BMC Fam Pract* 2004; 5:24. Abstract: **BACKGROUND:** Family doctors should care for individuals in the context of their family. Family has a powerful influence on health and illness and family interventions have been shown to improve health outcomes for a variety of health problems. The aim of the study was to investigate the Estonian family

doctors' (FD) attitudes to the patients' family-related issues in their work: to explore the degree of FDs involvement in family matters, their preparedness for management of family-related issues and their self-assessment of the ability to manage different family-related problems. **METHODS:** A random sample (n = 236) of all FDs in Estonia was investigated using a postal questionnaire. Altogether 151 FDs responded to the questionnaire (response rate 64%), while five of them were excluded as they did not actually work as FDs. **RESULTS:** Of the respondents, 90% thought that in managing the health problems of patients FDs should communicate and cooperate with family members. Although most of the family doctors agreed that modifying of the health damaging risk factors (smoking, alcohol and drug abuse) of their patients and families is their task, one third of them felt that dealing with these problems is ineffective, or perceived themselves as poorly prepared or having too little time for such activities. Of the respondents, 58% (n = 83) were of the opinion that they could modify also relationship problems. **CONCLUSIONS:** Estonian family doctors are favourably disposed to involvement in family-related problems, however, they need some additional training, especially in the field of relationship management.

Oosterlaan J, Geurts HM, Knol DL, Sergeant JA. Low basal salivary cortisol is associated with teacher-reported symptoms of conduct disorder. *Psychiatry Res* 2005; 134(1):1-10.

**Abstract:** Cortisol has been implicated in psychobiological explanations of antisocial behavior. This study measured basal salivary cortisol in a sample of 25 children (age range 6 to 12 years) selected to vary in levels of antisocial behavior. Regression analyses were used to predict cortisol concentrations from parent- and teacher-reported symptoms. Parent-reported symptoms did not predict basal cortisol. Teacher-reported conduct disorder (CD) symptoms explained 38% of the variance in the cortisol concentrations, with high symptom severity associated with low cortisol. When a distinction was made between aggressive and non-aggressive CD symptoms, aggressive CD symptoms were more clearly related to low cortisol than non-aggressive CD symptoms. In contrast to previous research, no evidence was found for a mediating role of anxiety symptoms in the relationship between CD and cortisol. The results support biologically based models of antisocial behavior in children that involve reduced autonomic activity.

Opperman S, Alant E. The coping responses of the adolescent siblings of children with severe disabilities. *Disabil Rehabil* 2003; 25(9):441-54. **Abstract:** **PURPOSE:** There is a paucity of literature conducted on adolescents' perceptions of their siblings with severe disabilities. The period of adolescence is characterized by personal and emotional conflicts resulting from teenagers' search towards self-identity and autonomy and exploration of the boundaries of parental support. The study attempts to describe the coping responses of these adolescent siblings in their adjustment to the family stressor of having a sibling with a disability; and the adolescents' available coping resources. **METHOD:** This study is qualitative in nature and open-ended, structured interviews were conducted with 19 adolescents between the ages of 12 and 15 years who had a sibling with severe disabilities. The interviews were then analysed according to categories using an editing analysis style. **RESULTS:** The results indicated that the subjects reported limited family interaction and were often reticent in expressing their feelings about their sibling with a disability. In addition, they expressed guilt feelings regarding their siblings with disabilities. Furthermore, siblings of children with severe disabilities received limited information and guidance regarding their sibling's disability. **CONCLUSION:** The need for professional support to facilitate adolescents' coping with the disability and its consequences as well as the establishment of strong support networks for these adolescents became evident.

Orekhova EV, Stroganova TA, Posikera IN. Alpha activity as an index of cortical inhibition during sustained internally controlled attention in infants. *Clin Neurophysiol* 2001; 112(5):740-9. **Abstract:** **OBJECTIVES:** The study examined the suggestion that infant ability to maintain attention in anticipatory task and to sustain interference is related to the active inhibitory processes in cortical neural networks. **METHODS:** The extent of selective EEG synchronization in the alpha range has been taken as a measure of cortical inhibition. EEG was registered in 60 infants aged 8-11 months during: (1) attention to an object in the visual field (externally controlled attention); (2) anticipation of the person in the peek-a-boo game (internally controlled attention). **RESULTS:** The infants who demonstrated longer periods of anticipatory attention had higher absolute spectral amplitude in the broad frequency range under both experimental conditions. It was suggested that the effect of 'overall' EEG synchronization is related to

some stable individual differences in psychophysiological traits. To control for the effect of overall EEG synchronization the relation between relative alpha amplitudes in 6.4-10 Hz range and the duration of internally controlled attention was analyzed. The infants with longer compared to shorter anticipatory attention spans had relatively higher 6.8 Hz alpha synchronization at posterior parietal sites under this experimental condition. CONCLUSIONS: It was suggested that alpha synchronization over posterior parietal cortex reflects an active inhibition of certain parietal networks involved in maintaining attention to peripheral visual field rather than merely an 'idle' state of this cortical area. Such an inhibition appears to allow infants to avoid interference of concurrent visual stimulation at the periphery of the visual field.

Orfali K. Parental role in medical decision-making: fact or fiction? A comparative study of ethical dilemmas in French and American neonatal intensive care units. *Soc Sci Med* 2004; 58(10):2009-22. Abstract: Neonatal intensive care has been studied from an epidemiological, ethical, medical and even sociological perspective, but little is known about the impact of parental involvement in decision-making, especially in critical cases. We rely here on a comparative, case-based approach to study the parental role in decision-making within two technologically identical but culturally and institutionally different contexts: France and the United States. These contexts rely on two opposed models of decision-making: parental autonomy in the United States and medical paternalism in France. This paternalism model excludes parents from the decision-making process. We investigate whether parental involvement leads to different outcomes from exclusively medically determined decisions or whether "technological imperatives" outplay all other factors to shape a unique, 'medically optimal' outcome. Using empirical data generated from extensive ethnographic fieldwork, in-depth interviews with 60 clinicians and 71 parents and chart review over a year in two neonatal intensive care units (one in France and one in the US), we analyze the factors that can explain the observed differences in decision-making in medically identical cases. Parental involvement and the legal context play a less role than physicians' differential use of certainty versus uncertainty in prognosis, a conclusion that corroborates the fact that medical control over ethical dilemmas remains even in the context of autonomy. French physicians do not ask parents permission to withdraw care (as expected in a paternalistic context); but symmetrically, American neonatologists (despite the prevailing autonomy model) tend not to ask permission to continue. The study provides an analysis of the making of "ethics", with an emphasis on how decisions are conceptualized as ethical dilemmas. The final conclusion is that the ongoing medical authority on ethics remains the key issue.

Ornoy A. The impact of intrauterine exposure versus postnatal environment in neurodevelopmental toxicity: long-term neurobehavioral studies in children at risk for developmental disorders. *Toxicol Lett* 2003; 140-141:171-81.

Abstract: Various investigators have shown that enriched environment may positively affect the early brain development of experimental animals. Environment was also shown to positively affect the development of young children born to mothers of low socio-economic class (low SES). It is unknown, however, to what extent can an enriched environment improve the developmental outcome of children born with slight brain damage. We studied the development of preschool and early school age children born to heroin dependent parents raised at home or adopted in comparison to children suffering only from environmental deprivation (low parental SES) and to controls. They were examined by several professionals, using standard, age appropriate, neurological and psychological tests. Similar evaluations were performed on a group of early school age children born to mothers with pregestational or with gestational diabetes and on a group of children born prematurely, with a birth weight of less than 1500 g using various developmental tests. Young children born to heroin dependent mothers and fathers raised at home and children of low SES had, in comparison to controls, lower intellectual skills and a higher rate of inattention. This persisted at school age, too. Children born to heroin dependent mothers adopted at a young age and hence being raised in a good environment had normal intellectual function but a high rate of inattention and behavioral problems. We also examined the school age children for possible presence of ADHD and found a high rate of ADHD among all children born to heroin dependent parents including those adopted, as well as in the children with low parental SES. Similar findings regarding the strong positive influence of an enriched environment were observed in children born to diabetic mothers, where the intellectual abilities of the children were directly related with parental education. The cognitive abilities of the children born prematurely were also strongly associated with parental education and not with the degree of perinatal complications. In conclusion, in all groups of children at high risk for developmental problems was found that the environment has a strong influence on their intellectual abilities but not on motor skills or attention span. A good environment (high parental SES) may significantly improve the outcome.

Ornoy A, Segal J, Bar-Hamburger R, Greenbaum C. Developmental outcome of school-age children born to mothers with heroin dependency: importance of environmental factors. *Dev Med Child Neurol* 2001; 43(10):668-75.

Abstract: Development of children aged 5 to 12 years born to mothers with heroin dependency raised at home or adopted was studied in comparison with: (1)

children with environmental deprivation alone (i.e. low parental socioeconomic status [SES] and evidence of neglect), (2) children born to fathers with heroin dependency fathers, and (3) control individuals of average SES. One hundred and sixty children (84 males and 76 females; average age at examination 8 years) were evaluated between 1998 and 1999. All were attending mainstream schools. All participants were examined by a paediatrician and a psychologist using standard neurological and psychological age-appropriate tests, as well as tests and questionnaires to assess learning ability and attention span. The Conners and Achenbach questionnaires and the Pollack Taper test were used to assess possible presence of attention-deficit-hyperactivity disorder (ADHD). Mothers were assessed for ADHD using Wender's questionnaire. Children born to parents with heroin dependency raised at home and those of low SES exhibited intellectual impairment both on verbal and performance skills. They also had impaired reading and arithmetic skills. Children born to mothers with heroin dependency but who were adopted at a young age had normal intellectual and learning abilities, except for some reduced function on the performance Wechsler Intelligence Scale for Children-Revised. We found a high rate of ADHD among all children born to parents with heroin dependency, including those adopted, as well as in children with low parental SES. The highest rate of ADHD was in children born to mothers with heroin dependency raised at home, being twice that observed in the other groups. Mothers of these groups of children also had a high rate of ADHD.

Ortenstrand A, Winbladh B, Nordstrom G, Waldenstrom U. Early discharge of preterm infants followed by domiciliary nursing care: parents' anxiety, assessment of infant health and breastfeeding. *Acta Paediatr* 2001; 90(10):1190-5.

Abstract: The aim of this study was to evaluate the effect of early discharge of preterm infants, followed by domiciliary nursing care, on the parents' anxiety, their assessment of infant health and breastfeeding. Seventy-five families including 88 preterm infants who were physiologically stable but in need of further special care, such as gavage feeding, were allocated to an early discharge group (EDG) that was offered home visits (n = 40), or to a control group offered standard neonatal care (CG) (n = 35). Seventy families (37 in the EDG and 33 in the CG) completed the study to the 1-y follow-up. Data were collected by means of questionnaires on three occasions: in the EDG, at

hospital discharge, on completion of the domiciliary care programme and after 1 y, and in the CG at the corresponding points in time, which were during hospitalization, at hospital discharge and after 1 y. No statistical differences were observed between the groups in emotional well-being, except that mothers in the EDG had a lower level of situational anxiety at the time of hospital discharge compared with CG mothers whose infants remained in hospital. One year after the birth, the EDG mothers said they had felt better prepared to take responsibility for the care of their babies after completion of the domiciliary care programme, in contrast to CG mothers. However, no statistical differences were observed in the recollection of anxiety, confidence in handling the baby and periods of mental imbalance. No statistical difference was observed in breastfeeding rates between the groups. Fathers in the EDG group tended to perceive their babies as being healthier, compared with CG fathers. CONCLUSION: Early discharge of preterm infants followed by domiciliary nursing care did not seem to have any major effect on the parents' anxiety and their assessment of infant health.

Osman M, Kebede Y, Anberbir S. Magnitude and pattern of injuries in north Gondar administrative zone, northwest Ethiopia. *Ethiop Med J* 2003; 41(3):213-20. Abstract: A prospective study was carried out between April and July 2000 in North Gondar administrative zone, Northwest Ethiopia, to assess the magnitude, pattern, outcome and burden of injuries. All trauma victims presenting to twenty health institutions were included. Of 37026 patients registered, 1982 (5.4%) presented with injury as main complaint. Trauma constituted about 46% of surgical patients, which shows a significant burden to the institutions. Seventy three percent of the injured patients were males. The leading cause of injury was assault (48.5%) followed by fall down injury (18.6%) and road traffic injuries (14.7%). Of the vehicle related injuries, 59.6% were caused by commercial vehicles. Admission was required in 15.2% of the injured patients. An average of 4.2 hours was required for initial outpatient management. The average hospital stay for the admitted patients was twelve and half days. In this and other parts of Ethiopia, injury prevention efforts should focus on assault, falls and transport safety with special attention to commercial vehicles. A community-based study is also recommended to explore the burden of trauma on the general community.

Overstreet K, Mannino FL, Benirschke K. The role of placental pathology in the evaluation of interpersonal violence: a case of abdominal gunshot wound in a 27-week gravid uterus. *J Perinatol* 2002; 22(8):675-8.

Abstract: We present a 17-year-old G1P0 Asian American woman with a previously undiagnosed pregnancy who sustained an intra-abdominal gunshot wound at 27 weeks' gestation. Within 2 hours of the traumatic event, the victim was taken emergently to the operating room for exploratory laparotomy. Findings included a gravid uterus with two entrance wounds and two small exit wounds with active bleeding from the right broad ligament. The fetus was bradycardic but viable, having suffered a gunshot wound to the left shoulder. Evaluation of the placenta revealed no sequelae from the acute event. Unexpectedly, two older, green, 7.0 cm retromembranous hematomas were present, both ringed by hemosiderin-laden macrophages. These hemorrhages clearly preceded the acute event. Although these findings seemed suspicious for a history of prior abuse or trauma, corroborative clinical data were unavailable at the time of initial placental evaluation. However, days later, the victim admitted to a history of interpersonal violence, with previous abuse from her boyfriend, a fatal victim of the same attack. The old retroplacental hemorrhages proved to be the only physical documentation of her previous abuse.

Owens PL, Hoagwood K, Horwitz SM *et al.* Barriers to children's mental health services. *J Am Acad Child Adolesc Psychiatry* 2002; 41(6):731-8. Abstract: OBJECTIVE: To examine the characteristics associated with barriers to children's mental health services, focusing on the effect of children's psychosocial problems on parents. METHOD: Data come from a first-grade, prevention-intervention project conducted in Baltimore, Maryland. Analyses were restricted to 116 families who participated in seventh-grade interviews and indicated the index child needed services. The Services Assessment for Children and Adolescents was used to measure barriers to children's mental health services. RESULTS: More than 35% of parents reported a barrier to mental health services. Types of barriers included those related to structural constraints, perceptions of mental health, and perceptions of services (20.7%, 23.3%, and 25.9%, respectively). Although parenting difficulties were associated with all barriers (structural: OR = 10.63, 95% CI: 2.37, 47.64; mental health: OR = 8.31, 95% CI: 1.99, 34.79; services: OR = 5.22, 95% CI: 1.56, 17.51), additional responsibilities related to attendance at meetings was associated only with structural barriers (OR = 5.49, 95% CI: 1.22, 24.59). CONCLUSIONS: Researchers and policymakers interested in increasing children's access to mental health services should consider strategies to reduce barriers related to perceptions about mental health problems and services, in addition to structural barriers. Particular attention should be given to programs that focus on the needs of families who are most affected by their child's psychosocial problems.

Oyserman D, Bybee D, Mowbray C, Hart-Johnson T. When  
757

mothers have serious mental health problems: parenting as a proximal mediator. *J Adolesc* 2005; 28(4):443-63.

Abstract: Maternal mental health (MMH) problems are associated with lack of confidence in one's parenting, overly lax or too harsh discipline, and child academic underperformance. We asked if parenting mediates the effect of MMH problems on academic outcomes even among mothers with serious mental illness (n=164). Structural equation analyses show a significant association between MMH problems and permissive (lack of parenting confidence, lack of follow through) parenting and verbal hostility as well as worse academic outcomes (school recorded grades, teacher reported behaviour). Permissive parenting completely mediated the direct effect of MMH on academic outcomes. Further analyses showed that the mediation effect was attributed to a single component of permissive parenting-lack of parenting confidence.

Paavilainen E, Astedt-Kurki P, Paunonen-Ilmonen M, Laippala P. Caring for maltreated children: a challenge for health care education. *J Adv Nurs* 2002; 37(6):551-7.

Abstract: AIM OF THE STUDY: The aim of this study was to establish whether paediatric nurses and doctors in a university hospital need supplementary training in the identification of child physical abuse and whether there is a need to develop health care education on child abuse issues. BACKGROUND: Child physical abuse was defined as actions of a parent or a primary caregiver of a child under 18 years of age, which have caused physical injuries to the child. METHODS: The sample consisted of paediatric staff (n=513) in a university hospital. Data were collected with a questionnaire, and the response rate was 62%. The data were analysed using statistical methods and quantitative content analysis. FINDINGS: Sixty per cent of respondents needed supplementary training in the identification of child abuse. Those having experience in caring for abused children considered the identification most difficult ( $P < 0.001$ ) and needed training more often ( $P < 0.005$ ) than the others. The need for training was explained by stating that their basic education had not addressed child abuse issues, and by the complexity of the issue. CONCLUSIONS: The findings indicate that research-based knowledge of the identification and treatment of child abuse should be incorporated into health care education. Supplementary education should address the management of complex and sensitive issues with customers, legislation, division of labour and multiprofessional collaboration in which nurses and doctors have an important, family wellbeing promoting role.

Paavola L, Kunnari S, Moilanen I. Maternal responsiveness and infant intentional communication: implications for the early communicative and linguistic development. *Child Care Health Dev* 2005; 31(6):727-35.

Abstract: BACKGROUND: Maternal responsiveness has been found to have an important role in early language acquisition. From early on, children can also be regarded as active participants in interaction who demonstrate increasing competence in conveying messages to their interactive partners. Hence, in order to demonstrate consistent effects of maternal responses, it is important to take into account individual differences among children. In the present study, the relation between the frequencies of maternal responses and infant intentional communicative acts as well as their predictive validity to subsequent early communicative and linguistic skills was examined. METHODS: The participants were 27 Finnish-speaking mothers and their healthy firstborn infants. Maternal and infant interactive behaviour was analysed from 20-min samples of free play collected during home visits at the infants' age of 10 months. At 12 months the children were assessed for their communicative and linguistic skills by using the Finnish version of the MacArthur Communicative Development Inventories and the Communication and Symbolic Behaviour Scales. RESULTS: The frequencies of maternal responses and infant intentional communicative acts were not intercorrelated. As for subsequent communicative and linguistic skills, the results of regression analyses indicated that both maternal responsiveness and infant intentional communication predict early comprehensive skills, whereas expressive skills--the use of both verbal and gestural communicative means--are predicted only by infant intentional communication. CONCLUSION: The results of the present study suggest that maternal responsiveness during the prelinguistic stage is not necessarily dependent on children's communicative competence. As predictors of early communicative and linguistic skills, both maternal responsiveness and infant intentional communication make a distinctive contribution.

Pacton S, Perruchet P, Fayol M, Cleeremans A. Implicit learning out of the lab: the case of orthographic regularities. *J Exp Psychol Gen* 2001; 130(3):401-26. Abstract: Children's (Grades 1 to 5) implicit learning of French orthographic regularities was investigated through nonword judgment (Experiments 1 and 2) and completion (Experiments 3a and 3b) tasks. Children were increasingly sensitive to (a) the frequency of double consonants (Experiments 1, 2, and 3a), (b) the fact that vowels can never be doubled (Experiment 2), and (c) the legal position of double consonants (Experiments 2 and 3b). The latter effect transferred to never doubled consonants but with a decrement in performance. Moreover, this decrement persisted without any trend toward fading, even after the massive amounts of experience provided by years of practice. This result runs against the idea that transfer to novel material is indicative of abstract rule-based knowledge and suggests instead the action of mechanisms sensitive to the statistical properties of the material. A

connectionist model is proposed as an instantiation of such mechanisms.

Paeglis C, Loftus-Hills A. Child protection: reflection on practice. *RCM Midwives* 2004; 7(6):246-7.

Pagani L, Jyrkinen L, Niinimäki J *et al.* A portable diagnostic workstation based on a Webpad: implementation and evaluation. *J Telemed Telecare* 2003; 9(4):225-9.

Abstract: A wireless hand-held Webpad device was used to review a sample set of cranial computerized tomography (CT) studies to assess its diagnostic capabilities and its feasibility as a portable diagnostic workstation for radiology. The data-set consisted of 30 head CT studies of emergency cases. Two neuroradiologists and a senior radiologist participated in the evaluation of the portable workstation. They used a Web-based viewer that we developed, which provided all the major functionalities required for radiological image review. The reported radiological findings and diagnoses were compared with a gold standard, comprising a set of diagnoses previously formulated by a consensus panel of radiologists who had reviewed the original studies. The diagnoses made using the Webpad were correct (no major discrepancies) in 82 out of 90 interpretations (91%), which is comparable to the accuracy reported in image review with a conventional radiological workstation. The average total working time per diagnosis was 5 min 25 s (range 2-12 min). The simplicity of use of the system and its low cost make it suitable for distributing radiological studies within hospital facilities.

Paget WJ, Meerhoff TJ, Meijer A. Epidemiological and virological assessment of influenza activity in Europe during the 2003-2004 season. *Euro Surveill* 2005; 10(4):107-11.

Notes: CORPORATE NAME: EISS

Abstract: The 2003-2004 influenza season in Europe was dominated by the spread of the new drift variant A/Fujian/411/2002 (H3N2)-like virus which was not perfectly matched with the A(H3N2) component of the influenza vaccine. Sporadic cases of this virus were detected in Europe at the end of the 2002-2003 season and influenza activity associated with this virus began relatively early during the 2003-2004 season. Generally, influenza activity first occurred in the west of Europe (Ireland, the United Kingdom and the Iberian Peninsula) in October/November and gradually moved east across Europe, affecting Latvia, Lithuania and Poland during the months of January and February 2004. In general, the intensity of clinical activity was higher than during the 2002-2003 season (in 13 out of 20 networks) and, in countries reporting age specific data, the highest consultation incidences were observed among children aged 0-14. However, despite the emergence of the A(H3N2) drift variant, clinical incidences were not especially high compared with

historical data. The composition of the 2004-2005 influenza vaccine has been modified compared with the 2003-2004 season and includes an A/Fujian/411/2002 (H3N2)-like virus strain and a new B virus strain (a B/Shanghai/361/2002-like virus).

Paine RW, Grossberg S, Van Gemmert AW. A quantitative evaluation of the AVITEWRITE model of handwriting learning. *Hum Mov Sci* 2004; 23(6):837-60. Abstract: Much sensory-motor behavior develops through imitation, as during the learning of handwriting by children. Such complex sequential acts are broken down into distinct motor control synergies, or muscle groups, whose activities overlap in time to generate continuous, curved movements that obey an inverse relation between curvature and speed. The adaptive vector integration to endpoint handwriting (AVITEWRITE) model of Grossberg and Paine (2000) [A neural model of corticocerebellar interactions during attentive imitation and predictive learning of sequential handwriting movements. *Neural Networks*, 13, 999-1046] addressed how such complex movements may be learned through attentive imitation. The model suggested how parietal and motor cortical mechanisms, such as difference vector encoding, interact with adaptively-timed, predictive cerebellar learning during movement imitation and predictive performance. Key psychophysical and neural data about learning to make curved movements were simulated, including a decrease in writing time as learning progresses; generation of unimodal, bell-shaped velocity profiles for each movement synergy; size scaling with isochrony, and speed scaling with preservation of the letter shape and the shapes of the velocity profiles; an inverse relation between curvature and tangential velocity; and a two-thirds power law relation between angular velocity and curvature. However, the model learned from letter trajectories of only one subject, and only qualitative kinematic comparisons were made with previously published human data. The present work describes a quantitative test of AVITEWRITE through direct comparison of a corpus of human handwriting data with the model's performance when it learns by tracing the human trajectories. The results show that model performance was variable across the subjects, with an average correlation between the model and human data of 0.89+/-0.10. The present data from simulations using the AVITEWRITE model highlight some of its strengths while focusing attention on areas, such as novel shape learning in children, where all models of handwriting and the learning of other complex sensory-motor skills would benefit from further research.

Paiva T, Coelho H, Araujo MT *et al.* Neurological teleconsultation for general practitioners. *J Telemed Telecare* 2001; 7(3):149-54. Abstract: A neurology teleconsulting network was implemented between a university hospital in Lisbon and five nearby health centres. PCs equipped for

videoconferencing were installed, connected by ISDN lines at 128 kbit/s. Fifty-three general practitioners (GPs) were surveyed. The survey showed that the GPs had difficulties in using computers, but they had definite intentions to use teleconsultation for neurology cases and 83% of the respondents stated that they would probably use the technique. During the study, 90 neurology teleconsultations took place over 55 weeks. The average consultation rate was 1.6 teleconsultations per week (SD 1.3, range 0-6). The conferences lasted 10-45 min. Longer teleconsultations were mainly due to technical difficulties in using computers on the part of users with a low level of computer literacy. The patients were 42 males and 46 females, with a mean age of 38 years (SD 20, range 1-84); two patients were discussed twice. The benefits consisted mainly of advice on patient medication, diagnosis and the prevention of unnecessary specialist consultations or laboratory examinations. Doctor-doctor teleconsultation allows the rapid resolution of queries which otherwise cause stress to patients and increase the cost and complexity of care.

Paivio SC. Stability of retrospective self-reports of child abuse and neglect before and after therapy for child abuse issues. *Child Abuse Negl* 2001; 25(8):1053-68. Abstract: OBJECTIVE: This study is a follow-up to a previously reported outcome study evaluating the efficacy of an emotionally focused therapy for adult survivors of childhood abuse. The present purpose was to evaluate the stability of self-reports of child maltreatment in the context of reduced psychopathology after therapy. The Childhood Trauma Questionnaire (CTQ; Bernstein et al., 1994) was used to measure the extent of child abuse and neglect. METHOD: The CTQ and measures of symptomatology, abuse resolution, and self-esteem were administered at pretreatment to 44 clients and after 6 months of therapy to 33 therapy completers. Post-treatment interviews also assessed changes in clients' perceptions of self and abusive and neglectful others. Analyses examined change on dependent measures, in interviews, and on the CTQ, as well as the test-retest and alpha reliabilities of CTQ factor scales, and the relationship of CTQ factor scales with pretreatment measures of distress. RESULTS: Analyses revealed significant reductions in psychopathology on all dependent measures and reduced self-blame, negatively biased memories, avoidance, and minimization of the abuse after therapy. Reports of abuse and physical neglect on the CTQ remained stable from pre- to post-therapy. All CTQ dimensions demonstrated good internal consistency and convergent validity with trauma-specific measures of distress. CONCLUSIONS: The stability of the CTQ in the context of significantly reduced psychopathology contributes to evidence supporting the accuracy of retrospective self-reports of childhood abuse.

Paivio SC, Laurent C. Empathy and emotion regulation:

reprocessing memories of childhood abuse. *J Clin Psychol* 2001; 57(2):213-26. Abstract: This article argues that therapist empathy is both an essential context and an active intervention for addressing the emotion regulation problems common among adult survivors of child abuse. We define healthy emotion regulation, the role of parental empathy in the development of these capacities, and the results of abuse and neglect as empathic failures. We define therapeutic empathy and outline how it functions both to modulate arousal and to increase client awareness of emotional experience, thus facilitating emotional processing of trauma memories.

Pakalnis A, Paolicchi J. Frequency of secondary conversion symptoms in children with psychogenic nonepileptic seizures. *Epilepsy Behav* 2003; 4(6):753-6. Abstract: We retrospectively identified 22 patients (19 were girls) with psychogenic nonepileptic seizures (NES) studied with video EEG telemetry over a 24-month period. A history of other conversion symptoms was identified in 11 of 22 patients. Symptoms were frequently neurological in nature. A strong association with depression and history of abuse was noted in children with multiple conversion manifestations. These NES patients with secondary conversion symptoms may require more intensive psychological therapy and be at risk for long-term pathology.

Pal D, Raut DK, Das A. A study of HIV/STD infections amongst commercial sex workers in Kolkata (India). Part-I: some socio-demographic features of commercial sex workers. *J Commun Dis* 2003; 35(2):90-5. Abstract: A community-based survey of Human Immunodeficiency Virus (HIV) and sexually transmitted diseases (STD) was carried out among commercial sex worker's (CSW) in different red light areas of Kolkata. By multistage random sampling technique 867 female sex workers (FSW) studied who were belonging to Sonagachi 77.28%, Metiabruz 14.07%, Rampurgali and Khidderpore 8.65% red light areas. Among sex workers surveyed 58.94% were Hindu and 33.33% Muslims. There were 22.07% CSW of foreign origin, out of which 17.99% from Bangladesh and 4.04% from Nepal. Majority of CSW 74.28% were under thirty years of age. The lowest age was 13 years and mean age was 26.55 years. There were 22.26% sex workers under twenty years and 6.92% above forty years of age. About 79.0% of sex workers were illiterate. The average number of clients visiting each sex workers was 2.67, with a range between 1 to 8 clients per day. The average duration for which sex workers remain in the trade was 6 to 7 years. Around 60.09% sex workers were in the trade for five years, while 2.64% were for more than twenty years. Average monthly income of sex workers was around Rs. 500-1000. History of pregnancy was present in 84.66% with one child in 24.91 % to maximum eight in 0.23% sex workers. The mean number of pregnancies was 1.9 per female sex workers.

About 36.2% had history of abortion and 65.51 % had living children.

Pal DK, Chaudhury G, Das T, Sengupta S. Predictors of parental adjustment to children's epilepsy in rural India. *Child Care Health Dev* 2002; 28(4):295-300. Abstract: BACKGROUND: Negative societal attitudes towards disability affect the adjustment of parents when their child is diagnosed with epilepsy. Recent studies have suggested that parental and child outcomes, including adjustment, can be influenced by non-directed social support to mothers of children with disability. The objective of our study was to test the hypothesis that maternal satisfaction with social support, measured at the beginning of treatment, would predict parental adjustment to the child's epilepsy after 1 year of treatment. METHODS: We enrolled 46 mothers of children aged 6-18 years with epilepsy in the study. We measured social support using the modified Dunst family support scale, and parental adjustment using a locally validated instrument (S-PAM). Correlation was tested using a multiple linear regression model, allowing for confounding variables. RESULTS: Parental adjustment at outcome was positively independently correlated with satisfaction with social support at baseline, and negatively with severity of the child's epilepsy. The regression model explained 34% of the total variance. CONCLUSIONS: Taken together with evidence from previous studies, this finding supports the idea that helping parents to find more satisfaction within their (new or existing) social networks will promote adjustment to their child's disability.

Palermo GB. Adult antisocial behavior following childhood abuse: a new protective factor? *Int J Offender Ther Comp Criminol* 2004; 48(6):635-7.

Palermo TM, Childs G, Burgess ES, Kaugars AS, Comer D, Kelleher K. Functional limitations of school-aged children seen in primary care. *Child Care Health Dev* 2002; 28(5):379-89. Abstract: OBJECTIVE: The purpose of the present study was to assess the prevalence of functional limitations in children seen in a large paediatric practice network and to identify sociodemographic, family and psychosocial factors related to functional limitations. STUDY DESIGN: Cross-sectional analysis. POPULATION: Children were recruited from two large, practice-based primary care research networks during their paediatric office visits. For the present study, participants included 14 630 school-aged children (ages 6-15 years) and their caregivers. OUTCOMES MEASURED: Parents completed written questionnaires including the Pediatric Symptom Checklist, the Family Apgar and the Functional Limitations Index. RESULTS: Findings indicated that 15% of children surveyed had some limitation in their daily functioning. More children had schoolwork and

physical function limitations than limitations in personal and self-care. Logistic regression equations predicted functional limitations and health status in children from a model of sociodemographic factors, psychosocial symptoms and family functioning. CONCLUSIONS: A low but significant number of school-age children seen in the primary care setting experience functional limitations. Children with any psychosocial symptoms were at increased risk for functional limitations, indicating the critical need to screen for functional impairment in children with suspected behavioural or emotional problems. A screening tool of functional limitations may be useful for assessing the presence or absence of such limitations in children's daily function and warrants further investigation.

Palermo TM, Valenzuela D, Stork PP. A randomized trial of electronic versus paper pain diaries in children: impact on compliance, accuracy, and acceptability. *Pain* 2004; 107(3):213-9.

Abstract: Electronic diary assessment of pain and disability has become increasingly popular in adult chronic pain research but use of this methodology with children has received limited attention. The aim of this study was to compare two formats of a prospective daily diary (handheld computer=e-diary; paper diary=p-diary) on children's compliance, accuracy, and acceptability ratings. Sixty children, ages 8-16 (M=12.3) with headaches or juvenile idiopathic arthritis, were randomized to receive either e-diaries administered via home visits (n=30) or p-diaries (n=30) handed out during clinic visits for return by mail. Results demonstrated significant mean differences in diary entries completed between groups, with children with e-diaries completing more days (M=6.6) compared to children with p-diaries (M=3.8),  $P<0.001$ . Diaries returned by children in the p-diary group contained significantly more errors and omissions compared to diaries returned by children in the e-diary group (which contained none),  $P<0.001$ . Children rated both diary formats as highly acceptable and easy to use. A significant gender x diary format interaction ( $P<0.01$ ) was found for compliance where boys demonstrated greater compliance with the e-diary format. Findings demonstrated that the e-diary was feasible to use with children and showed significantly greater compliance and accuracy in diary recording compared to traditional paper diaries in a population of children with recurrent pain.

Pallesh O, Saltzman K, Koopman C. Internet use and attitudes towards illicit internet use behavior in a sample of Russian college students. *Cyberpsychol Behav* 2004; 7(5):553-8.

Abstract: This study assessed Internet use and attitudes toward illicit use of the Internet in a sample of Russian college students. A sample comprised of 198 students was recruited from a university in Moscow. Each participant completed a survey assessing demographic

characteristics, Internet use, and attitudes towards engaging in illicit behaviors over the Internet. About half of the students reported that they used the Internet at least several times a year, with 8% reporting daily use of the Internet. Among Internet users, most reported having Internet access either at home or at a friends' home, and 16 % reported having Internet access from work, school, or a computer center. Among Internet users, the main purpose was for school-related activities (60%), followed by e-mail (55%), entertainment (50%), chatting (24%), and searching for pornography (6%). Although most students thought it was inappropriate to read someone else's e-mail, use someone else's password or credit card information without their permission, or break into someone's computer, many students did endorse those illicit behaviors. Over a fifth of the students reported that they knew hackers. Forty three percent of students agreed that people make too much fuss about watching videos, movies or downloading music on the Internet without paying. Males were more likely than females to report using the Internet for entertainment purposes ( $p = 0.006$ ) and were more likely to agree that it was okay to break into someone's computer ( $p = 0.04$ ). The results of this study suggest that these Russian college students predominately use the Internet to help with their schoolwork, to communicate with others, and for entertainment. These results also suggest that interventions may be useful to change attitudes endorsing illicit uses of the Internet.

Palmieri TL, Aoki T, Combs E *et al.* Saturday-morning television: do sponsors promote high-risk behavior for burn injury? *J Burn Care Rehabil* 2004; 25(4):381-5; discussion 372-3.

Abstract: Television has become an important tool for learning and socialization in children. Although television violence has been associated with adverse effects, data on depiction of fire and burn injury are lacking. We sought to determine whether Saturday-morning television programming, viewed primarily by children, depicts fire and burn injury as safe or without consequence, thus potentially increasing the incidence of burn injury in children. This was a prospective observational study. Saturday-morning children's television programs were videotaped from 7 AM to 11 AM for eight different television networks during a 6-month period. Tapes were scored for scenes depicting fire or smoke by independent observers. Recorded items included show category, scene type, gender target, context of fire, and outcome after exposure to flame. Fire events were documented during programs and their associated commercials. A total of 108 hours of children's programs, 16 hours per network, were recorded. Scenes depicting fire or smoke were identified 1960 times, with 39% of events occurring during the program itself and 61% in commercials. Fire was depicted as either safe or without consequence in 64% of incidents. Action adventure stories accounted for 56% of flame depictions. Overall, one incident

involving flame and fire was portrayed for each 3 minutes of television programming. Saturday-morning television programming frequently depicts fire as safe, empowering, or exciting. The incidence of flame use in programming varies between stations but is most prevalent in action/adventure stories. Television commercials, although brief, provide the majority of the misinformation regarding fire. Medical professional societies should alert the public to this potential hazard and recommend responsible portrayal of fire in children's television programming.

Pan RJ, Littlefield D, Valladolid SG, Tapping PJ, West DC. Building healthier communities for children and families: applying asset-based community development to community pediatrics. *Pediatrics* 2005; 115(4 Suppl):1185-7.

Abstract: Social capital is the power of social networks and relationships, which constitute the social environment. Social capital has been associated with many measures of health and development. Asset-based community development (ABCD) provides a framework to increase social capital and build stronger, healthier communities for children. ABCD is a strength-based approach to community building that emphasizes bringing together community assets including individual community members, voluntary associations, and institutions. How pediatricians can apply ABCD to child health is described.

Panchaud C, Woog V, Singh S, Darroch JE, Bankole A. Issues in measuring HIV prevalence: the case of Nigeria. *Afr J Reprod Health* 2002; 6(3):11-29. Abstract: This article reviews methodologies and data sources that have been used to measure HIV prevalence and sexual behaviours associated with the transmission of HIV in Nigeria. The review includes 35 studies on HIV prevalence and methodology and 34 studies on sexual behaviour published between 1990 and 2000. As at 1999, 5.1-5.4% of the general population was estimated to be infected with HIV. Trend data, although limited, indicate that HIV prevalence is increasing among both the general population and specific subgroups. Data on sexual behaviours indicate that risk behaviours are very common in Nigeria while condom use remains low. Studies in local areas and on population subgroups indicate great variability in both HIV prevalence and sexual risk behaviour. Comparability of data is limited as a result of differences in design and measurement across studies. Also, there is a dearth of information on certain groups at high risk for HIV. Despite efforts to establish and improve HIV surveillance in Nigeria, this review illustrates limitations and challenges undoubtedly shared by other countries.

Paolucci EO, Genuis ML, Violato C. A meta-analysis of the published research on the effects of child sexual abuse. *J Psychol* 2001; 135(1):17-36.

Abstract: A meta-analysis of the published research on the effects of child sexual abuse (CSA) was undertaken for 6 outcomes: posttraumatic stress disorder (PTSD), depression, suicide, sexual promiscuity, victim-perpetrator cycle, and poor academic performance. Thirty-seven studies published between 1981 and 1995 involving 25,367 people were included. Many of the studies were published in 1994 (24; 65%), and most were done in the United States (22; 59%). All six dependent variables were coded, and effect sizes ( $d$ ) were computed for each outcome. Average unweighted and weighted  $d$ s for each of the respective outcome variables were .50 and .40 for PTSD, .63 and .44 for depression, .64 and .44 for suicide, .59 and .29 for sexual promiscuity, .41 and .16 for victim-perpetrator cycle, and .24 and .19 for academic performance. A file drawer analysis indicated that 277 studies with null  $d$ s would be required to negate the present findings. The analyses provide clear evidence confirming the link between CSA and subsequent negative short- and long-term effects on development. There were no statistically significant differences on  $d$ s when various potentially mediating variables such as gender, socioeconomic status, type of abuse, age when abused, relationship to perpetrator, and number of abuse incidents were assessed. The results of the present meta-analysis support the multifaceted model of traumatization rather than a specific sexual abuse syndrome of CSA.

Papanikolaou EG, Plachouras N, Drougia A *et al.* Comparison of misoprostol and dinoprostone for elective induction of labour in nulliparous women at full term: a randomized prospective study. *Reprod Biol Endocrinol* 2004; 2:70. Abstract: BACKGROUND: The objective of this randomized prospective study was to compare the efficacy of 50 mcg vaginal misoprostol and 3 mg dinoprostone, administered every nine hours for a maximum of three doses, for elective induction of labor in a specific cohort of nulliparous women with an unfavorable cervix and more than 40 weeks of gestation. MATERIAL AND METHODS: One hundred and sixty-three pregnant women with more than 285 days of gestation were recruited and analyzed. The main outcome measures were time from induction to delivery and incidence of vaginal delivery within 12 and 24 hours. Admission rate to the neonatal intensive care unit within 24 hours post delivery was a secondary outcome. RESULTS: The induction-delivery interval was significantly lower in the misoprostol group than in the dinoprostone group (11.9 h vs. 15.5 h,  $p < 0.001$ ). With misoprostol, more women delivered within 12 hours (57.5% vs. 32.5%,  $p < 0.01$ ) and 24 hours (98.7% vs. 91.4%,  $p < 0.05$ ), spontaneous rupture of the membranes occurred more frequently (38.8% vs. 20.5%,  $p < 0.05$ ), there was less need for oxytocin augmentation (65.8% vs. 81.5%,  $p < 0.05$ ) and fewer additional doses were required (7.5% vs. 22%,  $p < 0.05$ ). Although not statistically significant, a

lower Caesarean section (CS) rate was observed with misoprostol (7.5% vs. 13.3%,  $p > 0.05$ ) but with the disadvantage of higher abnormal fetal heart rate (FHR) tracings (22.5% vs. 12%,  $p > 0.05$ ). From the misoprostol group more neonates were admitted to the intensive neonatal unit, than from the dinoprostone group (13.5% vs. 4.8%,  $p > 0.05$ ). One woman had an unexplained stillbirth following the administration of one dose of dinoprostone. CONCLUSIONS: Vaginal misoprostol, compared with dinoprostone in the regimens used, is more effective in elective inductions of labor beyond 40 weeks of gestation. Nevertheless, this is at the expense of more abnormal FHR tracings and more admissions to the neonatal unit, indicating that the faster approach is not necessarily the better approach to childbirth.

Papin T, Houck T. All it takes is leadership. *Child Welfare* 2005; 84(2):299-310.

Abstract: The authors, as leaders in a public child welfare system, have teamed together and reached out to their private sector partners in a large, rural county in western Colorado. This effort was part of a comprehensive, communitywide effort to redesign and fundamentally improve the entire child welfare service delivery system. Across the country in many areas where collaboration and integration have been the focus, we often hear voices in the private and public sector declaring the importance of integration. Why, then, does it not happen as a general course of action? The authors believe the answer lies in leadership, both public and private. They hold the Mesa County model up as witness to that fact.

Papworth S, Cartlidge P. Learning from adverse events - the role of confidential enquiries. *Semin Fetal Neonatal Med* 2005; 10(1):39-43.

Abstract: National confidential enquiries collect data on adverse events to identify shortfalls and improve future clinical care; they also highlight inadequacies in service organisation. This article focuses on the work of the Confidential Enquiry into Maternal Deaths (CEMD) and the Confidential Enquiry into Stillbirths and Deaths in Infancy (CESDI).

Paquette D, Laporte L, Bigras M, Zoccolillo M. [Validation of the French version of the CTQ and prevalence of the history of maltreatment]. *Sante Ment Que* 2004; 29(1):201-20.

Abstract: This study demonstrates that the five maltreatment scales in the long and short versions of the CTQ are valid and usable with French-speaking populations. It also shows emotional neglect to be the most common form of maltreatment in its general population sample, and physical neglect to be the least common. Physical, emotional and sexual abuse prevalences in the convenience sample roughly correspond to the rates generally obtained in non-clinical samples. Finally, women in the sample display

greater co-occurrence of different forms of maltreatment, especially involving sexual abuse, than men.

Paradise JL, Dollaghan CA, Campbell TF *et al.* Otitis media and tympanostomy tube insertion during the first three years of life: developmental outcomes at the age of four years. *Pediatrics* 2003; 112(2):265-77. Abstract: OBJECTIVE: In a long-term, prospective study, we set out to determine whether otitis media in the first 3 years of life persisting for periods currently considered developmentally threatening actually results in later impairments of children's cognitive, language, speech, or psychosocial development; whether prompt insertion of tympanostomy tubes prevents or lessens any such impairments; and whether, irrespective of causality, associations exist between persistent early-life otitis media and later developmental impairments. This report describes findings in study participants at the age of 4 years. METHODS: We enrolled 6350 healthy infants from 2 to 61 days of age at urban hospitals and 2 small-town/rural and 4 suburban private pediatric practices. We regularly evaluated the children for the presence of middle-ear effusion (MEE) throughout their first 3 years of life by pneumatic otoscopy, supplemented by tympanometry; we monitored the validity of the otoscopic observations on an ongoing basis; and we treated children for otitis media according to specified guidelines. In the clinical trial component of the study, we randomly assigned 429 children who met specified minimum criteria regarding the persistence of MEE to undergo tympanostomy tube insertion either promptly or after a defined extended period if MEE remained present. In the associational component of the study, we selected a representative sample of 241 children who ranged from having no MEE to having MEE the cumulative duration of which fell just short of meeting randomization criteria for the clinical trial. In 397 (92.5%) of the children in the clinical trial and in 234 (97.1%) of the children in the representative sample, we assessed cognitive, language, speech, and psychosocial development at the age of 4 years, using formal tests, conversational samples, and parent questionnaires. RESULTS: In children in the randomized clinical trial, there were no statistically significant differences in mean (+/-standard deviation) scores (higher denotes more favorable) favoring the early-treatment group over the late-treatment group on the General Cognitive Index of the McCarthy Scales of Children's Abilities (97 +/- 14 and 98 +/- 14, respectively); the Peabody Picture Vocabulary Test-Revised, a measure of receptive language (90 +/- 15 vs 92 +/- 16); the Nonword Repetition Test, a measure of phonological memory (66 +/- 12 vs 70 +/- 12); the Number of Different Words, a measure of word diversity (150 +/- 34 vs 150 +/- 31); the Mean Length of Utterance in Morphemes, a measure of sentence length and grammatical complexity (3.4 +/- 0.8 vs 3.4 +/- 0.7); or the Percentage of Consonants Correct-

Revised, a measure of speech-sound production (92 +/- 5 vs 93 +/- 5). There were also no significant differences in ratings (higher denotes less favorable) on the Parenting Stress Index-Short Form (Total Stress scores: 68 +/- 18 vs 65 +/- 17) or the Child Behavior Checklist (Total Problem T scores: 50 +/- 10 vs 49 +/- 10). In the associational component of the study, correlations between the children's durations of MEE and their developmental outcomes were generally weak and, in most instances, nonsignificant. Exceptions, after adjustment for sociodemographic variables and for hearing thresholds at the time of developmental testing, consisted of a significant negative correlation between children's cumulative durations of MEE in their first 3 years of life and scores on the McCarthy Verbal subscale, and significant positive correlations between durations of MEE and scores on 2 measures of parent-child stress. The percentage of variance in these scores explained by time with MEE beyond that explained by sociodemographic variables ranged from 1.6% to 3.3%. In both the randomized clinical trial and the associational component, sociodemographic variables seemed to be the most important factors influencing developmental outcomes, and in both components, the results at 4 years of age were consistent with the results that had been obtained at 3 years of age. CONCLUSIONS: In otherwise healthy children who are younger than 3 years and have persistent MEE within the duration limits that we studied, prompt insertion of tympanostomy tubes does not measurably improve developmental outcomes at 4 years of age. In such children, persistent MEE within the duration limits that we studied is negligibly associated with and probably does not affect developmental outcomes at 4 years of age.

Parent AS, Rasier G, Gerard A *et al*. Early onset of puberty: tracking genetic and environmental factors. *Horm Res* 2005; 64 Suppl 2:41-7. Abstract: Under physiological conditions, factors affecting the genetic control of hypothalamic functions are predominant in determining the individual variations in timing of pubertal onset. In pathological conditions, however, these variations can involve different genetic susceptibility and the interaction of environmental factors. The high incidence of precocious puberty in foreign children migrating to Belgium and the detection in their plasma of a long-lasting 1,1,1-trichloro-2,2-bis(4-chlorophenyl) ethane (DDT) residue suggest the potential role of environmental endocrine disrupting chemicals in the early onset of puberty. This hypothesis was confirmed by experimental data showing that temporary exposure of immature female rats to DDT *in vivo* results in early onset of puberty. We compared the gene expression profile of hypothalamic hamartoma associated or not with precocious puberty in order to identify gene networks responsible for both hamartoma-dependent sexual precocity and the onset of normal human puberty. In conclusion, pathological variations in the

timing of puberty may provide unique information about the interactions of either environmental conditions or genetic susceptibility with the hypothalamic mechanism controlling the onset of sexual maturation, as shown by examples of precocious puberty following exposure to endocrine disrupters or due to hypothalamic hamartoma.

Parizel PM, Ceulemans B, Laridon A, Ozsarlak O, Van Goethem JW, Jorens PG. Cortical hypoxic-ischemic brain damage in shaken-baby (shaken impact) syndrome: value of diffusion-weighted MRI. *Pediatr Radiol* 2003; 33(12):868-71. Abstract: Shaken-baby syndrome (SBS) is a type of child abuse caused by violent shaking of an infant, with or without impact, and characterized by subdural hematomas, retinal hemorrhages, and occult bone fractures. Parenchymal brain lesions in SBS may be missed or underestimated on CT scans, but can be detected at an earlier stage with diffusion-weighted MRI (DW-MRI) as areas of restricted diffusion. We demonstrate the value of DW-MRI in a 2-month-old baby boy with suspected SBS. The pattern of diffusion abnormalities indicates that the neuropathology of parenchymal lesions in SBS is due to hypoxic-ischemic brain injuries, and not to diffuse axonal injury.

Parker MH, Forbes KL, Findlay I. Eugenics or empowered choice? Community issues arising from prenatal testing. *Aust N Z J Obstet Gynaecol* 2002; 42(1):10-4. Notes: GENERAL NOTE: KIE: KIE Bib: genetic screening; prenatal diagnosis Abstract: The prevention of inherited disabilities is viewed in two contrasting ways--either as enhancing reproductive choice and improving population health, or as discriminating against disabled community members. We argue that modern clinical genetics,

including preimplantation genetic diagnosis (PGD), reflects a persistent and defensible desire by the community to prevent disability, rather than as increasing discrimination or threatening to produce a 'new eugenic' society. Screening should be presented as a distinct issue for decision-making about the prevention or acceptance of disability, rather than as a routinely accepted component of antenatal care. The community must improve its understanding of the experiences of those who manage disability, and continue to debate the issues of discrimination, selective genetic prevention and enhancement, reproductive freedom, and eugenics.

Parkes J, Donnelly M, Dolk H, Hill N. Use of physiotherapy and alternatives by children with cerebral palsy: a population study. *Child Care Health Dev* 2002; 28(6):469-77.

Abstract: **OBJECTIVES:** To describe the use of physiotherapy services and alternative therapies by a population of children with moderate to severe cerebral palsy (CP). **DESIGN:** Descriptive cross-sectional survey. **SUBJECTS:** A total of 212 parents of children aged 4-14 years with moderate to severe CP were identified from the Northern Ireland Cerebral Palsy Register (NICPR) and a random subsample of their paediatric physiotherapists. **MAIN MEASURES:** A standardized description of motor impairment or assessment form; a postal questionnaire to parents and paediatric physiotherapists (to validate parents' reports of service use). **RESPONSE RATES:** In total, 85% of parent questionnaires were returned and 100% of paediatric physiotherapists responded. **RESULTS:** Service use among families was high; on average the families had contact with approximately seven services in a 6-month time interval. The overwhelming majority of children (96%) received physiotherapy during the school term and most (59%) received treatment at least twice a week for 30 min; 43% of children had their physiotherapy discontinued over the summer holidays. Over one-quarter (28%) of families had opted out of the NHS and bought alternatives like conductive education (21%) or private forms of conventional physiotherapy (16%). Children with more severe forms of CP, in special education, particularly at schools for physical disability, were high-intensity users of the physiotherapy service. Despite this, 74% of parents wanted more physiotherapy for their child. **CONCLUSIONS AND IMPLICATIONS:** The demand for physiotherapy services is likely to continue given the relatively stable prevalence rate of CP, the proportion of children with disabling CP and the level of parent interest in the service. A number of quality aspects and gaps in the service have been identified.

Parra GR, Martin CS, Clark DB. The drinking situations of adolescents treated for alcohol use disorders: a psychometric and alcohol-related outcomes investigation. *Addict Behav* 2005; 30(9):1725-36. Abstract: Psychometric properties of the Inventory of

Drinking Situations (IDS) were examined using a sample of adolescents with Alcohol Use Disorders (AUDs; N = 352; mean age=16.6; 65.6% boys). Relations of drinking situations to alcohol-related outcomes 1 and 3 years following treatment also were investigated. Consistent with the higher-order structure of the IDS reported in adult samples, findings indicated that a 3 factor solution provided the best fit to the data: Negative (alpha = .98), Social (alpha = .95), and Temptation (alpha = .84) Situations. With regard to convergent and discriminate validity, evidence suggested that the Negative Situations subscale was related more strongly to an indicator of negative emotionality than to an indicator behavioral undercontrol. Conversely, the Social Situations subscale was associated more strongly with an indicator of behavioral undercontrol than an indicator of negative emotionality. Social and temptation drinking situations were associated with alcohol-related outcomes 1 year following treatment, but this was generally not the case 3 years following treatment. These results indicate that the IDS is a reliable and valid measure for use with adolescents receiving treatment for alcohol-related problems.

Parra GR, O'Neill SE, Sher KJ. Reliability of self-reported age of substance involvement onset. *Psychol Addict Behav* 2003; 17(3):211-8.

Abstract: The authors investigated the reliability of self-reported age of onset (AO) for alcohol, tobacco (cigarette), and illicit drug involvement. Participants were 410 young adults taking part in an 11-year longitudinal study. A moderate degree of reliability was found for the 3 substances. Despite this level of stability, results illustrate a tendency for reported AOs to increase over time. The trend is more salient for participants who reported younger AOs at the initial assessment. Findings also indicate that, for alcohol and tobacco, more individuals were classified as early onset based on Year 1 compared with Year 11 reports. Despite these systematic changes, at least for alcohol and illicit drugs, age at which onset was assessed did not moderate the association between AO and substance-related outcomes.

Pascalis O, de Haan M, Nelson CA. Is face processing species-specific during the first year of life? *Science* 2002; 296(5571):1321-3.

Abstract: Between 6 and 10 months of age, the infant's ability to discriminate among native speech sounds improves, whereas the same ability to discriminate among foreign speech sounds decreases. Our study aimed to determine whether this perceptual narrowing is unique to language or might also apply to face processing. We tested discrimination of human and monkey faces by 6-month-olds, 9-month-olds, and adults, using the visual paired-comparison procedure. Only the youngest group showed discrimination between individuals of both species; older infants and adults only showed evidence of discrimination of their

own species. These results suggest that the "perceptual narrowing" phenomenon may represent a more general change in neural networks involved in early cognition.

Pascual-Castroviejo I, Pascual Pascual SI, Ruza-Tarrio F, Viano J, Garcia-Segura JM. [Battered baby syndrome. Report of a case with severe sequelae]. *Rev Neurol* 2001; 32(6):532-5.

Abstract: OBJECTIVE. To present a case with shaken-baby syndrome after having seizures and respiratory problems. CLINICAL CASE. A previously normal child of 7 months of age presented an acute picture of status epilepticus with respiratory problems and periods of apnea. He was studied with electroencephalography, computerized tomography, magnetic resonance (MR) imaging and spectroscopic-MR. The child showed the presence of small subdural and epidural hematomas in both frontal regions 24 hours after the onset of the problem. The follow-up with MR studies revealed voluminous subdural bilateral hygroma that increased the size along the following six months, despite treatment with bilateral subdural-peritoneal shunt, and the patient showed infantile spasms. At 8 years of age, the patient shows severe mental retardation with autistic behavior and blindness, though he is able to walk without help and he has not seizures. The subdural hygroma decreased the size, but MR shows severe cortico-subcortical atrophy of both parieto-occipital regions. Spectroscopic MR study discloses severe neuronal loss and gliosis. CONCLUSIONS. The shaken-baby syndrome causes severe encephalopathy and vision problems, blindness in many cases, after showing voluminous subdural and/or epidural hematomas which lead to a severe neuronal loss and gliosis. Shaken-baby syndrome is not always associated with skull fracture nor is necessarily related with battered-child syndrome.

Patel AM. Appropriate consent and referral for general anaesthesia - a survey in the Paediatric Day Care Unit, Barnsley DGH NHS Trust, South Yorkshire. *Br Dent J* 2004; 196(5):275-7; discussion 271.

Notes: GENERAL NOTE: KIE: 7 refs. GENERAL NOTE: KIE: KIE Bib: informed consent/minors

Abstract: BACKGROUND: In November 1998 the General Dental Council introduced guidelines for dental practitioners when referring a patient for general anaesthesia (GA). The practitioner is required to explain the risks associated with GA and the alternatives, give a detailed medical history and a clear justification for providing GA in the letter of referral. METHOD: A survey was administered on 202 parents or guardians, which aimed to investigate whether they felt that their dental practitioners had advised them of any risks of GA prior to referral. A record was also made if any reasons were given for the provision of GA in the letter of referral. RESULTS: The majority of the parents or guardians (66%) felt that they were not informed of any of the risks of GA and 25% felt that

they were. From the letters of referral, 37% contained a reason for GA and 63% did not give any reason or justification for GA. CONCLUSION: There is evidence that referring practitioners do not adequately explain the risks of the anaesthetic to parents or guardians of children undergoing GA. There is also a lack of clear justification in the letters of referral for providing GA. PRACTICE IMPLICATION: It is essential that the alternatives and the risks of GA are discussed and if GA is still required, a clear justification should be contained in the letter of referral as part of informed consent. More importantly the referring practitioner should keep a contemporaneous record of this, preferably with a signature from the parent or guardian on agreement of referral.

Paterson J, Tukuitonga C, Butler S, Williams M. Infant bed-sharing among Pacific families in New Zealand. *N Z Med J* 2002; 115(1154):241-3.

Abstract: AIM: To describe infant bed-sharing among Pacific families in New Zealand. METHODS: The data were gathered as part of the Pacific Island Families: First Two Years of Life (PIF) Study in which 1376 mothers were interviewed when their infants were six-weeks-old. Maternal reports of infant bed-sharing practices were assessed by questions about infant sleep location and the number of people who usually shared a mattress with the infant. RESULTS: Over half of the mothers (54.9%) reported that their infants shared a mattress with other people, 44.2% sharing with one other person, the remainder sharing with two or more people. Of the bed-sharing infants, 4.7% slept on a mattress on top of the bed, and 4.7% only slept part of the night in the shared bed. CONCLUSIONS: Together with effective information delivery, the educational and housing issues that many Pacific families in New Zealand face need to be addressed so that parents can make informed decisions about infant care practices.

Patric D. Safeguarding children through police checks: a discussion. *Paediatr Nurs* 2004; 16(9):36-8.

Patterson GR, DeGarmo D, Forgatch MS. Systematic changes in families following prevention trials. *J Abnorm Child Psychol* 2004; 32(6):621-33.

Abstract: A selective prevention design was applied to 238 recently separated families. Of these, 153 mothers randomly assigned to the experimental (E) group participated in 14 group sessions focused on Parent Management Treatment (PMT). Prior analyses showed that, over time, the group of families in the untreated group deteriorated in both parenting practices and in child outcomes. In keeping with the classic prevention pattern, families in the E group showed modest improvements in parenting and in child outcomes. Improvements in parenting were associated with

significant reductions in problem behavior. The data showed that those mothers who improved their parenting skills during the first 12 months also showed significant reductions in maternal depression during that same interval. A cross-lagged panel analysis showed that a reduction in maternal depression during the first year of the study was a significant predictor of maintenance or improvements over the next 18 months. The findings are consistent with the concept of the family as a system.

Paul B, Bryant JA. Adolescents and the internet. *Adolesc Med Clin* 2005; 16(2):413-26, x. Abstract: The interactive, multimedia nature of the Internet makes it a potentially invaluable resource for adolescents. These same characteristics also mean that the Internet could be a potentially hazardous medium for certain members of this age group. Although the Internet allows adolescents access to an unprecedented amount of content in an endless number of areas, it also allows them access to content that many parents and caregivers find particularly objectionable. This article addresses several primary benefits and potential hazards associated with adolescent Internet use. It describes general trends in adolescent Internet use and considers how the medium allows individuals to extend their social networks and create new ones. Several ideas for maximizing the potential benefits and minimizing any potential harms are presented.

Pauli-Pott U, Mertesacker B, Beckmann D. Predicting the development of infant emotionality from maternal characteristics. *Dev Psychopathol* 2004; 16(1):19-42. Abstract: Few studies have examined the associations between environmental conditions and developing infant emotionality or the differential susceptibility to those conditions. The present longitudinal study aims to make a contribution to close that gap. We analyzed whether positive emotionality, negative emotionality/irritability, and withdrawal/fear at the end of the first year of life are predictable from preceding caregiver's depression/anxiety, social support, and sensitivity in the interaction with the infant while controlling for antecedent states of emotionality. Furthermore, the question of whether associations between maternal characteristics and subsequent fear are stronger in the subgroup of infants high in irritability as opposed to those who are low in irritability was investigated. Subjects were 101 healthy firstborn infants and their primary caregivers. Assessments were conducted at infant ages of 4, 8, and 12 months. Depression, anxiety, and the social support of the caregiver were assessed by questionnaire. Sensitivity in the caregiver-infant interaction was assessed by behavior observations within the scope of home visits. Temperament characteristics were observed in standardized laboratory episodes. Whereas negative emotionality and withdrawal/fear were significantly predictable from the maternal characteristics, no predictability could be shown for

developing positive emotionality. There were indications of a stronger association between the maternal characteristics and developing withdrawal/fear in irritable infants.

Payne CA. The evolution of community involvement in public health community-based efforts: a case study. *J Health Soc Policy* 2001; 14(2):55-70. Abstract: It is the opinion of many practitioners and analysts of public health efforts that community involvement is necessary to improve local health status. The nature of community involvement, however, can vary among projects, among sites in the same project and through time in the same site. Clear conceptions of community involvement assist in foreseeing the potential activities, outcomes and challenges of any particular community-based effort. Himmelman's concepts of community betterment and community empowerment offer a useful framework when community-involvement entails the direct participation of local organizations and constituencies. These two concepts are the ends of a continuum whereby in the movement from a community betterment to a community empowerment effort, there is an increase in community ownership and self-determination over all aspects of a project. This paper presents an empirical investigation of one community-based public health effort which instances a movement from community betterment to community empowerment.

Paz I, Jones D, Byrne G. Child maltreatment, child protection and mental health. *Curr Opin Psychiatry* 2005; 18(4):411-21. Abstract: PURPOSE OF REVIEW: This review summarizes advances in our understanding of child maltreatment and the implications thereof for physical, psychological and social development, with special emphasis on mental health aspects. RECENT FINDINGS: Methodological problems persist. These may be related in part to an over-emphasis on type of maltreatment, to the detriment of consideration of degree and extent of maltreatment. They may also be related to inadequate application of a comprehensive model of maltreatment and its consequences. Recent studies underline the inter-relatedness and cross-over between different types of child maltreatment and family violence. Research also underlines the extent to which child maltreatment is a major public health crisis internationally. Effects are seen on physical health and development as well as mental health, and it is becoming increasingly evident that these outcomes are inextricably linked to one another. There are encouraging signs that certain interventions are effective. SUMMARY: There is a need for a more sophisticated model of child maltreatment that includes not only degree but also the extent to which basic developmental needs are overridden when children are maltreated, and that includes children's responses to maltreatment as a mediating influence. More studies

are needed of samples of children who have been maltreated in order to gain a better understanding of how maltreatment distorts the trajectory of normal development. Crucially, we need more research on intervention, including both case management and psychological treatment approaches.

Pearn J, Gardner-Thorpe C. James Parkinson (1755-1824): a pioneer of child care. *J Paediatr Child Health* 2001; 37(1):9-13.

Abstract: James Parkinson (1755-1824) of Parkinson's disease, is well recognized as a pioneer of clinical neurology; and is even more famous as a founder of modern palaeontology. We have reviewed from primary sources his extensive contributions to clinical child care and his pioneering advocacy for child welfare, protection and safety. His writings, outreach and advocacy for children's health characterizes him as one whose influence was an important springboard from which evolved the modern specialty of paediatrics. Parkinson was one of the first to write on child-rearing practices and in this context antedated Benjamin Spock by 150 years. Parkinson was a pioneer of child safety and the prevention of childhood trauma. He wrote of the resuscitation of near-drowned children and of first aid for injured children. This critical analysis reviews his pioneering description of child abuse and the development of post-abuse hydrocephalus. He wrote the datum description (in English) of the pathophysiology and pathology of appendicitis in children, of fatal rabies in children and highlighted the risk of death even when the biting dog was not clinically rabid. His advocacy for social reform for children's welfare was courageous and pioneering. James Parkinson, hitherto unacknowledged, was a significant founder of the evolving discipline of paediatrics and child health.

Pears KC, Fisher PA. Emotion understanding and theory of mind among maltreated children in foster care: evidence of deficits. *Dev Psychopathol* 2005; 17(1):47-65.

Abstract: Children in foster care are at heightened risk for poor psychosocial outcomes. This study examined differences in two areas that may be associated with many of these outcomes, emotion understanding and theory of mind, using a sample of 3- to 5-year-old maltreated foster children (n = 60) and a comparison group of same-aged, low-income, nonmaltreated children living with their biological families (n = 31). Being in foster care was significantly associated with worse emotion understanding and theory of mind capabilities, even when accounting for age,

intelligence, and executive function. There were no significant associations between length of time in foster care, number of transitions, and emotion understanding and theory of mind. Results help to expand knowledge about the cognitive and affective deficits of children in foster care and suggest that interventions targeted at these deficits include an emphasis on emotion understanding and theory of mind.

Pedersen W, Hegna K. Children and adolescents who sell sex: a community study. *Soc Sci Med* 2003; 56(1):135-47.

Abstract: Adolescents who reported to have given sexual favors for payment were investigated. The sample consisted of all adolescents in the public and private school systems in Oslo, the capital in Norway (age group 14-17, response rate 94.3%, N=10,828). Adolescents who had sold sex form 1.4%, three times as many boys as girls. Half the group had done it more than 10 times. Most were under the legal age of sex in Norway (16 years) when this first happened. We found no associations with sociodemographic variables or residential area in Oslo. However, sex sale was associated with low intercourse debut age, conduct problems, alcohol problems, use of drugs (including heroin) and violent victimization. The conclusion is that a small group in the general adolescent population sells sex, and many of the clients are assumed to be homosexual or bisexual men. Adolescents who take part in these activities are often heavily involved in delinquent behaviors and use of drugs, and many probably are in a risk zone for sexually transmitted diseases (including HIV), drug abuse and a delinquent and criminal development.

Pedersen W, Mastekaasa A, Wichstrom L. Conduct problems and early cannabis initiation: a longitudinal study of gender differences. *Addiction* 2001; 96(3):415-31.

Abstract: AIM. To investigate the relationship between early conduct problems and early onset of cannabis use, with special emphasis on possible gender differences. DESIGN. A prospective longitudinal study of a national sample of 2436 adolescents. The sample was followed up over a year and a half, when the adolescents were in their early teens. SETTING. Norway. MEASUREMENTS. On the basis of an earlier study, conduct problems (CP) closely related to the criteria for conduct disorder (CD) in DSM-III-R were decomposed into three dimensions, labelled serious, aggressive and covert. Further, information was collected about alcohol intoxication, daily smoking and use of cannabis. A number of questions were posed about sexual interactions and perceived puberty development. Parental socio-economic status was measured according to the ISCO-88. Separate information was collected as to whether the parents were on social welfare or unemployed. A parental bonding measure (PBI) was used to measure the emotional relationship between respondents and

parents. Further, a measure of parental monitoring was used, and information was also collected on other aspects of the family milieu, and on the adolescents' peers. Statistical models. Logistic regression analysis was employed. As the sample consisted of pupils clustered within classes within schools, a three-level error structure for the logistic regression model was estimated. FINDINGS. There was a strong association between early conduct problems and subsequent cannabis initiation. Also conduct problems at a potential subclinical level seemed to have great impact. The effect was significantly stronger in girls than in boys. Serious CP was found to have a moderate effect upon cannabis initiation in boys, whereas aggressive and covert CP had strong effects in girls. Early onset of puberty and early sexual involvement had no impact, whereas early use of cigarettes proved an important precursor to cannabis use. CONCLUSIONS. Conduct problems are important precursors of early onset cannabis use, but probably represent gender-specific aetiologies. There might be an important potential for prevention of early onset drug use in the prevention of early conduct problems, in particular for girls.

Pedersen W, Samuelsen SO. [New patterns of sexual behaviour among adolescents]. *Tidsskr Nor Laegeforen* 2003; 123(21):3006-9. Abstract: BACKGROUND: We wanted to investigate erotic and sexual behaviour in adolescents, with emphasis on the trend over the last decade. MATERIALS AND METHODS: Two large, survey-based representative studies of Norwegian adolescents (each with approx. 11 000 respondents) from 1992 and 2002 (response rates 97% and 92%). FINDINGS: Median age at first intercourse has decreased by 12 months in females over this ten-year time span (to 16.7 years), while the decrease among males was more modest. Furthermore, oral sex now has the same prevalence as coitus from the mid-teen years on and seems to be introduced at the same point in time. Finally, females are as inclined as males to break the norm of being in love as the basis for a sexual relationship. INTERPRETATION: More adolescents are now sexually active and more risky sexual behaviour might be a consequence. However, the findings also suggest increased gender equality and a new cohort of more sexually active and self-confident females.

Peele PB, Lave JR, Kelleher KJ. Exclusions and limitations in children's behavioral health care coverage. *Psychiatr Serv* 2002; 53(5):591-4. Abstract: OBJECTIVE: The objective of this study was to identify benefit limits, diagnostic exclusions, and service exclusions of private behavioral health care plans that can influence the delivery of care to children. METHODS: A total of 128 commercial, employment-based behavioral health plans were examined for types of benefit limits, service exclusions, and diagnostic exclusions applicable to children. RESULTS: Almost

half of the plans had restrictions on the number of outpatient visits, with limits ranging from 12 to 60 clinic visits a year. More than half of the plans had limitations on the number of inpatient days, ranging from 20 to 60 days a year. Diagnoses excluded from coverage included autism, mental retardation, problems related to child abuse, and impulse control disorders, such as kleptomania and pyromania. Half of the services excluded could be categorized as either social and human services or complementary medicine rather than as mental health care. CONCLUSIONS: Plans commonly had service and diagnostic exclusions that could disrupt children's health care. The results of the study emphasize a need to address the types of treatment covered by mental health insurance.

Peeters F, Wessel I, Merckelbach H, Boon-Vermeeren M. Autobiographical memory specificity and the course of major depressive disorder. *Compr Psychiatry* 2002; 43(5):344-50.

Abstract: This study examined the stability of autobiographical memory dysfunction (i.e., difficulties in retrieving specific memories) during the course of major depressive disorder, its relation to early adverse experiences, and its influence on the course of depressive disorder. Using the Autobiographical Memory Test (AMT), specificity of autobiographical memory was assessed in 25 subjects with a current depressive disorder at baseline, and at 3 and 7 months follow-up. Also, information about self-reported childhood traumatization, and demographic and clinical variables was obtained. Autobiographical memory performance was relatively stable over time despite clinical improvement in the sample. It was not related to depression severity at baseline, while higher levels of childhood traumatization were correlated with more specific memory performance to negative cue words at baseline, but not during follow-up. Specific autobiographical responses to negative cue words predicted a better prognosis, whereas specific responses to positive cue words were not related to prognosis. Autobiographical memory dysfunction in depression appears to be stable over time, is related to short-term prognosis in depression, and may act as a vulnerability factor that influences the long-term course of depressive disorders.

Pelias MK, Markward NJ. Newborn screening, informed consent, and future use of archived tissue samples. *Genet Test* 2001; 5(3):179-85. Notes: GENERAL NOTE: KIE: 25 refs. GENERAL NOTE: KIE: KIE Bib: genetic research; genetic screening; human experimentation/informed consent

Abstract: Recent advances in genetic technologies have combined with established protocols for genetic screening to provide immense benefits to individuals and the public. In most American jurisdictions, newborn screening is mandated by law and does not require parental consent for the collection or testing of

the blood samples. Screening programs have been successful in identifying affected infants at an early stage for effective treatment of some genetic diseases. The public health benefit of screening programs is recognized and affirmed. However, collections of surplus, stored samples have become immensely attractive to researchers in medical genetics and the biomedical sciences. As geneticists have sought access to the newborn screening samples, they have recognized concerns related to whether they should use the samples, and, if so, under what conditions. This paper addresses the ethical issues associated with genetic screening and recommends an informed consent protocol that may be used to balance individual and parental rights with the interests of researchers who wish to use surplus samples in studies of genetic disease.

Pelkonen M, Marttunen M. Child and adolescent suicide: epidemiology, risk factors, and approaches to prevention. *Paediatr Drugs* 2003; 5(4):243-65. Abstract: Suicide is rare in childhood and early adolescence, and becomes more frequent with increasing age. The latest mean worldwide annual rates of suicide per 100 000 were 0.5 for females and 0.9 for males among 5-14-year-olds, and 12.0 for females and 14.2 for males among 15-24-year-olds, respectively. In most countries, males outnumber females in youth suicide statistics. Although the rates vary between countries, suicide is one of the commonest causes of death among young people. Due to the growing risk for suicide with increasing age, adolescents are the main target of suicide prevention. Reportedly, less than half of young people who have committed suicide had received psychiatric care, and thus broad prevention strategies are needed in healthcare and social services. Primary care clinicians are key professionals in recognizing youth at risk for suicide. This article reviews recent population-based psychological autopsy studies of youth suicides and selected follow-up studies of clinical populations and suicide attempters, analyzing risk factors for youth suicides. As youth suicides are rare, research on risk factors for youth suicidal ideation and attempted suicide is also briefly reviewed. The relationship between psychiatric disorders and adolescent suicide is now well established. Mood disorders, substance abuse and prior suicide attempts are strongly related with youth suicides. Factors related to family adversity, social alienation and precipitating problems also contribute to the risk of suicide. The main target of effective prevention of youth suicide is to reduce suicide risk factors. Recognition and effective treatment of psychiatric disorders, e.g. depression, are essential in preventing child and adolescent suicides. Research on the treatment of diagnosed depressive disorders and of those with suicidal behavior is reviewed. In the treatment of youth depression, psychosocial treatments have proved to be useful and efficacious. Although studies on the effectiveness of selective serotonin

reuptake inhibitors are limited in number, evidence supports their use as first-line antidepressant medication in youth depression. Available evidence suggests that various treatment modalities are useful in the treatment of suicidal youths, e.g. cognitive behavioral therapy and specialized emergency room interventions. Much of the decrease in suicide ideation and suicide attempts seems to be attributable to nonspecific elements in treatment. For high-risk youth, providing continuity of care is a challenge, since they are often noncompliant and commonly drop out or terminate their treatment prematurely. Developing efficacious treatments for suicidal children and adolescents would offer better possibilities to prevent suicides.

Pellai A, Castelli B, Scyslowska G *et al.* [Child sexual abuse primary prevention: outcome evaluation of a health education project implemented in Milan's elementary schools]. *Ann Ig* 2003; 15(5):529-39. Abstract: The study we present is aimed at evaluating the efficacy of a child sexual abuse prevention program that involved children attending 4th and 5th grade in Milan's (Italy) elementary schools. The project involved 53 classes (10 of 4th, 43 of 5th grade) during school year 2000-2001. Children filled a questionnaire before the beginning of the project and two months after the end; the questionnaire evaluates children's perception of risk and their self-efficacy skills in adopting protective strategies when involved in at risk situations. Final analysis has involved 674 children, 51.8% girls, 48.2% boys; 19.6% of children attended 4th grade, 80.4% 5th grade. Percentage of children that recognize the potential danger in the suggested at-risk situation is higher in post-test than in pre-test (87.9% vs 73.2%) and the number of them that does not adopt any self-defence strategy decreases (from 35.3% to 21.0%). The project increased the number of children that know body puberal changes (from 16.0% to 32.8%). According to these results it is evident that the program increased children's capacity to recognize and use self defence strategies in at risk situations. These results call for a potential extension and replication of this health education program.

Pennington DJ, Lonergan GJ, Mendelson KL. How well do we prepare pediatric radiologists regarding child abuse? Results of a survey of recently trained fellows. *Pediatr Radiol* 2004; 34(1):59-65. Abstract: BACKGROUND: Pediatric radiologists serve an important role in the radiologic diagnosis, investigation, and in legal proceedings in cases of child abuse. The Society for Pediatric Radiology should evaluate and insure the adequacy of training of pediatric radiologists for this important role. OBJECTIVE: The Society for Pediatric Radiology Committee on Child Abuse, 2002, conducted a 24-question survey to evaluate the scope and perceived adequacy of training received by pediatric radiology fellows regarding the radiologic diagnosis of child

abuse and the associated legal process. **MATERIALS AND METHODS:** Eighty-four surveys were mailed to radiologists who had completed a year in pediatric radiology fellowship training during the years 1999 and 2000. There were 33 surveys returned for an overall response of 39%. **RESULTS:** Respondents' perception of adequacy of training was best for the radiologic diagnosis of child abuse. The majority perceived they were not well trained in the investigative and legal processes regarding child abuse. The majority would welcome standardized training. **CONCLUSION:** Current pediatric radiology training programs do not sufficiently prepare pediatric radiologists for their role in the legal system regarding child abuse. A standardized program to train pediatric radiologists about the imaging diagnosis of child abuse and their role in the legal system is recommended.

Penson RT, Amrein PC. Faith and freedom: leukemia in Jehovah Witness minors. *Onkologie* 2004; 27(2):126-8.

Perera H, Rodrigo GD. Met and unmet needs of children with epilepsy in a paediatric tertiary care setting. *Ceylon Med J* 2004; 49(1):11-4. **Abstract:** **OBJECTIVE:** To investigate the extent to which the health needs were met or unmet in children with epilepsy attending a tertiary care outpatient setting. **PATIENTS AND METHOD:** A semi-structured interview was used to collect relevant information from the parents. It focused on ascertaining the quality of health care received by the children, including the extent to which attention was given to epilepsy related physical, behavioural, social and educational impairments that were identified by the parents. **RESULTS:** There was satisfactory seizure control in the majority. Most children received only one anticonvulsant and side-effects were reported to be minimal. A large majority had behavioural problems, and social and educational difficulties to a lesser extent. Parents were concerned about the implications of these problems, but there was little communication about them in the doctor-patient contact. Even where the problems were communicated, parent satisfaction about the interventions was low. Parents identified the availability of more consultation time and provision of more information on epilepsy as their expectations from doctors. **CONCLUSIONS:** This study shows that awareness and communication about the multiple health problems of children with epilepsy are necessary to improve the quality of health care given to them.

Perez A, Scribano PV, Perry H. An intentional opiate intoxication of an infant: when medical toxicology and child maltreatment services merge. *Pediatr Emerg Care* 2004; 20(11):769-72. **Abstract:** We present an instructive case of a 5-week-old infant seen in the emergency department with acute inspiratory stridor and depressed level of consciousness. His emergency department course

identified an acute opiate intoxication. The child also developed chest wall rigidity, a rare complication of narcotic use. We discuss the emergency department management, as well as the toxicologic and child protection investigations.

Perez-Albeniz A, de Paul J. Dispositional empathy in high- and low-risk parents for child physical abuse. *Child Abuse Negl* 2003; 27(7):769-80. **Abstract:** **OBJECTIVE:** The present study was designed to investigate dispositional empathy in high-risk parents for child physical abuse, using self-report instruments. More specifically, the objective was to know if high-risk parents for child physical abuse, in comparison with low-risk parents, show deficits on main dimensions of dispositional empathy: empathic concern, role-taking, and personal distress. **METHOD:** Based on their scores on the Abuse Scale of the CAP Inventory (Milner, 1986), 36 high-risk and 38 low-risk for child physical abuse participants were selected from a total sample of 440 Basque Country (Spain) general population parents. Both groups were statistically matched on sociodemographic variables. The Interpersonal Reactivity Index (IRI, Davis, 1980), the Hogan Empathy Scale (HES, Hogan, 1969) and the Questionnaire Measure of Emotional Empathy (QMEE, Mehrabian & Epstein, 1972) were used to assess dispositional empathy. **RESULTS:** As expected, high-risk, relative to low-risk, parents showed lower total scores on the HES and QMEE measures and lower scores on the IRI "Empathic concern" dimension. Moreover, high-risk, relative to low-risk, parents showed higher scores on the IRI "Personal distress" dimension. No differences between groups were observed for the IRI "Perspective-taking" dimension. **CONCLUSIONS:** Findings of the present study supported the hypothesis that high-risk parents for child physical abuse show a deficit in dispositional empathy. High-risk parents reported less feelings of warmth, compassion and concern for others and more feelings of anxiety and discomfort that result from observing another's negative experience.

Perez-Albeniz A, de Paul J. Gender differences in empathy in parents at high- and low-risk of child physical abuse. *Child Abuse Negl* 2004; 28(3):289-300. **Abstract:** **OBJECTIVES:** The present research was designed to study empathy in high-risk parents for child physical abuse. The main objective was to study if high-risk mothers and fathers, compared to low-risk mothers and fathers, presented more Personal distress, less Perspective-taking, less Empathic concern and a deficit in dispositional empathy toward their partner and children. **METHOD:** Based on their scores on the Abuse Scale of the CAP Inventory [J.S. Milner, The Child Abuse Potential Inventory: Manual, 2nd ed., Psytec Corporation, Webster, NC], 19 (9 fathers and 10 mothers) high- and 26 (12 fathers and 14 mothers) low-risk parents for child physical abuse were selected from a total sample of 331 parents of the Spanish general

population. Both groups were statistically matched on sociodemographic variables. The Interpersonal Reactivity Index (IRI) [Catalog of Selected Documents in Psychology 10 (1980) 85] and the Parent/Partner Empathy Scale (PPES) [N.D. Feshbach, N. Caskey, A new scale for measuring parent empathy and partner empathy: factorial structure, correlates and clinical discrimination, 1985] were used to assess dispositional empathy. RESULTS: An interaction between risk status and gender for "Personal distress" and "Perspective-taking" was found. High-risk mothers for child physical abuse showed more "Personal distress" than low-risk mothers and low-risk fathers. High-risk fathers for child physical abuse showed less "Perspective-taking" than low-risk mothers and low-risk fathers. No difference between both groups was found for the IRI "Empathic concern" dimension. Moreover, high-risk, compared to low-risk, parents showed lower scores both on the "Empathy toward the partner" and on the "Empathy toward the child" dimensions of the PPES. No interaction between risk status and gender was found for the PPES dimensions. CONCLUSIONS: Findings of the present study supported the hypothesis that high-risk parents for child physical abuse show a deficit both in general empathy and in empathy toward their family members. Moreover, findings suggested the existence of a different pattern of deficits in empathy for high-risk fathers and high-risk mothers.

Perez Alonso EJ. [Critical considerations on the legal regulation of sex selection (II)]. *Law Hum Genome Rev* 2002; (17):99-124.

Perez-Ciordia I, Catalan Fabo F, Zalacain Nicolay F, Barriendo Antonanzas M, Solaegui Diaz de Gueren R, Guillen Grima F. [Profile of the Emergency demand and influence of televised soccer games on an extra-hospital center in the Tafalla health care district. Navarre, Spain]. *Rev Esp Salud Publica* 2003; 77(6):735-47.

Abstract: BACKGROUND: The demand placed on both hospital as well as extrahospital emergency care units currently continues to increase at a growing rate. This study has a twofold objective: the quantification and study of the personal characteristics of the users who are demanding emergency care and assessing whether televised soccer games have any bearing on the utilization of emergency care services. METHODS: A longitudinal descriptive study (9,723 users demanding care) and study of cases and controls (1,284 users demanding care) according to whether or not a soccer game was being televised by means of a logistic regression model. The associations were quantified by means of the odds ratio (OR). Those dealt with by telephone or in infirmaries were not included in the study. RESULTS: A total 10.6% of the demand involved home visits, 4.8% of this total having been sent to hospital. A total 13.3% of the demand corresponds to individuals visiting from other

healthcare districts, a total of 65 being overusers of emergency care (8 or more visits). The month of August (32.3%). Sundays (44.56%) and the 12:00 p.m.-2:00 p.m. timeframe (8.38%) are the times when the greatest demand for care occurs, the differences being statistically significant. Televised soccer games were associated to a 19.8% ( $p < 0.001$ ) rise in demand as compared to the control period. CONCLUSIONS: A high degree of use of the extrahospital emergency care units has been found to exist, a major part of the demand being concentrated at highly specific points in time. A major degree of care is provided to those visiting from outside their own healthcare districts. Television soccer game broadcasts is associated with the greater utilization of the emergency care services.

Perez-Duenas B, Valls-Sole J, Fernandez-Alvarez E *et al.* Characterization of tremor in phenylketonuric patients. *J Neurol* 2005; 252(11):1328-34. Abstract: Tremor of unknown origin is detected in 10-30% of early-treated and in more than 30% late-treated phenylketonuric patients. With the aim of characterizing tremor in phenylketonuria, we carried out a systematic study in 54 patients aged 6 to 37 years. Tremor examination was done by applying the WHIGET Tremor Rating Scale and by accelerometer recording (BYOPAC System MP100WSW). Age at diet onset, IQ test results, concomitant plasma phenylalanine levels and index of dietary control were also studied. Tremor was not observed at rest in any case, but was apparent in 22 patients (40.7%) when carrying out a kinetic task. In 15 patients tremor was also evident during maintenance of a postural task at a frequency ranging between 7.5 and 12.7 Hz. Frequency of tremor was not significantly modified by loading the arms or by increasing muscle contraction. Patients with tremor had a later age at onset of phenylalanine restricted diet ( $p < 0.001$ ). Other treatment-related variables did not differ between patients with and without tremor. Our results of the neurophysiological examination suggest that tremor in phenylketonuric patients is dependent on a dysfunction of central nervous system networks and may be an index of cerebral damage.

Perez-Olmos I, Fernandez-Pineres PE, Rodado-Fuentes S. [The prevalence of war-related post-traumatic stress disorder in children from Cundinamarca, Colombia]. *Rev Salud Publica (Bogota)* 2005; 7(3):268-80. Abstract: OBJECTIVE: Determining the prevalence of post-traumatic stress disorder (PTSD) related to the type of war exposure and associated factors in school-aged children from three Colombian towns. METHODS: Cross-sectional epidemiological study. Representative randomised sample of 493 children aged 5-14. The children were evaluated during 2002 using semi-structured psychiatric interviews and the clinician administered PTSD scale. 167 children were evaluated in La Palma who had been chronically exposed to war, 164 in Arbelaez who had had recent

war-exposure and 162 in Sopo who had not been exposed to war. War-related PTSD prevalence was calculated in each municipality. Odds ratio (OR) and chi-square were used for evaluating the association between exposure to war and PTSD and the related risk. Multivariate analysis used the logistic regression model. The affected children required specialised mental health counselling. **RESULTS:** The prevalence of PTSD resulting from war was 16,8 % in La Palma, 23,2 % in Arbelaez and 1.2% in Sopo. A 19.9 OR (CI 4.7, 119.2), 30,5 Chi-square and  $p = 0.000$  revealed war-related PTSD association and risk for children when comparing the exposed towns to Sopo. The logistic regression showed that geographical closeness to war zone and intense emotional reaction to war increased the probability of war-related PTSD. Vulnerability factors were predominant in war-exposed towns. Poverty, parents' low educational level and child abuse predominated in La Palma. Attention-deficit and psychosomatic disorders were more prevalent in Arbelaez. **CONCLUSIONS:** War affects children's mental health; the children from the exposed towns had 19 times greater probability of war-related PTSD than those from a non-exposed town. Early therapeutic intervention is a public health priority. The results are useful for countries suffering from war, internal conflict and/or terrorism.

Perfumo F, Martini A. Lupus nephritis in children. *Lupus* 2005; 14(1):83-8.  
 Abstract: In systemic lupus erythematosus renal involvement is more frequent in children than in adults. Overall, 60-80% of children with systemic lupus erythematosus have urinary or renal function abnormalities early in the disease course. In 90% of patients, renal disease occurs within two years from disease onset. Clinically significant renal involvement ranges from asymptomatic urinary findings to nephrotic syndrome and renal failure. Long-term prognosis is similar to that observed in adults. Treatment aspects that are peculiar to children include drug side-effects, such as growth inhibition induced by steroids, the need to consider morbidity-related issues with respect to the very long life expectancy of patients and the problems related to the impact of disease in adolescents. The recent availability of a childhood SLE definition of improvement and the presence of large international paediatric rheumatology networks should, in the future, facilitate the implementation of controlled clinical trials devoted to paediatric SLE.

Perry MU, Collins-Willard R, Smock WS. Responding to sexual violence: critical issues for healthcare providers.

*J Ky Med Assoc* 2005; 103(9):436-41.  
 Abstract: Sexual violence is a monumental problem in Kentucky and elsewhere, and healthcare providers play a critical role in its identification, treatment, and prevention. This article provides essential information for physicians treating survivors of sexual violence, including treatment options, protocol for medical-forensic examinations, tips for documentation, and information about community resources that can facilitate treatment outcomes and provide follow-up services.

Persson EK, Dykes AK. Parents' experience of early discharge from hospital after birth in Sweden. *Midwifery* 2002; 18(1):53-60.  
 Abstract: **OBJECTIVE:** to investigate the factors that influence the experience of mothers and fathers when they have chosen to return home, earlier than is the normal routine, following the birth of their baby. **DESIGN:** a qualitative study, using open interviews, was undertaken. The text of the transcripts was coded and categorised according to the grounded theory method using constant comparative analysis. **SETTING:** interviews were carried out with 12 parents, six mothers and six fathers, individually in their own homes. They had all left a maternity/family ward at the Helsingborg Hospital in southern Sweden within 26 hours of birth whereas the normal discharge time is 72 hours. **MEASUREMENTS AND FINDINGS:** 'a sense of security' was the core category. Achieving a sense of security linked to informed choice for early discharge appeared to be dependent on the following categories: (1) the midwives' empowering behaviour; (2) affinity within the family; (3) the parents' right to autonomy/control; (4) physical well-being. There appears to be an inner connection between each of these categories. **KEY CONCLUSIONS:** the midwife's empowering behaviour supports the parents' sense of security and encourages their informed choice of earlier discharge after birth. When the mothers' and babies return home it strengthens the affinity within the family and the father's sense of participation.

Peters RD, Petrunka K, Arnold R. The Better Beginnings, Better Futures Project: a universal, comprehensive, community-based prevention approach for primary school children and their families. *J Clin Child Adolesc Psychol* 2003; 32(2):215-27.  
 Abstract: Evaluated a community-based, universal project designed to prevent emotional and behavioral problems and promote general development in young children, while also attempting to improve family and neighborhood characteristics, to link effectively with existing services, and to involve local residents in project development and implementation. The research involved 554 4-year-old children and their families living in 3 disadvantaged neighborhoods in Ontario, Canada. Longitudinal analyses of changes over the first 5 years of project operation indicated significant improvements in children's and parents' social-

emotional functioning and physical health, parenting behaviors, and neighborhood and school characteristics. The findings from the Better Beginnings, Better Futures Project are encouraging and provide unique evidence for the extent to which a universal, comprehensive, community-based prevention strategy can promote the longer term development of young children, their families, and their neighborhoods.

Peters RJ Jr, Tortolero SR, Addy RC *et al.* The relationship between sexual abuse and drug use: findings from Houston's Safer Choices 2 program. *J Drug Educ* 2003; 33(1):49-59.

Abstract: Self-report drug use data were collected from 282 female alternative school students surveyed through the Safer Choices 2 study in Houston, Texas. Data collection took place between October 2000 and March 2001 via audio-enabled laptop computers equipped with headphones. Logistic regression analyses indicated that sexual abuse history was significantly associated with lifetime use (OR = 1.9,  $p < 0.05$ ). While the relationships tested in this study are exploratory, they provide evidence for an important connection between sexual abuse and substance use among female alternative school students.

Peterson C, Ringner M. Analyzing tumor gene expression profiles. *Artif Intell Med* 2003; 28(1):59-74.

Abstract: A brief introduction to high throughput technologies for measuring and analyzing gene expression is given. Various supervised and unsupervised data mining methods for analyzing the produced high-dimensional data are discussed. The main emphasis is on supervised machine learning methods for classification and prediction of tumor gene expression profiles. Furthermore, methods to rank the genes according to their importance for the classification are explored. The approaches are illustrated by exploratory studies using two examples of retrospective clinical data from routine tests; diagnostic prediction of small round blue cell tumors (SRBCT) of childhood and determining the estrogen receptor (ER) status of sporadic breast cancer. The classification performance is gauged using blind tests. These studies demonstrate the feasibility of machine learning-based molecular cancer classification.

Petkova V, Dimitrova Z. Asthma, drug medication and noncompliance. *Boll Chim Farm* 2002; 141(5):355-6.

Abstract: According to the new concepts, asthma is a chronic disease of the upper respiratory tracts, caused by different cells, including the mastocites and eosinophils. The patients that are suffering from episodic, frequent, or chronic asthma are participating very energetic in the treatment--they have to know and control the symptoms of their disease and also to possess technical skills to perform the treatment. **METHODOLOGY:** Between March 1 and July 31,

1999, 30 patients [19 women and 11 men, mean age 35 years (range 2.50 to 65)], followed at the Clinic for Allergic Diseases of the University hospital "Aleksandrovska", Medical University of Sofia, Bulgaria, were interviewed blindly in order to assess their compliance with pharmacologic therapy. All patients were suffering from different types of asthma. **RESULTS:** The level of compliance among the studied group of patients is 86%. In comparison with the literary data where the level of non-compliance is 20% the obtained level is lower--14%. The reasons for non-compliance according to the patients are: the appearance of ADRs, the high price of the drugs, the hard application of the drug form.

Petrunik M, Weisman R. Constructing Joseph Fredericks: competing narratives of a child sex murderer. *Int J Law Psychiatry* 2005; 28(1):75-96.

Abstract: Joseph Fredericks--one of Canada's most notorious sex offenders--was defined through the institutions that dealt with him from his infancy to his death to the inquest held after his death. In this paper, we locate in historical context and compare the different narratives that were constructed of his life in each of these institutional settings from unwanted child to 'mental defective' to psychiatric offender to criminal recidivist to victim to iconic sexual predator. We show that each of these narratives claimed to capture the essence of Fredericks in terms of what were his core characteristics and what remedies were necessary for the problems he posed only to be superseded by new narratives based on different assumptions. Finally, we show how one of these conceptions of Frederick's essence influenced a shift in Canadian public policy for sex offenders toward the greater emphasis on community protection characteristic of public policy in the United States.

Petry NM, Steinberg KL. Childhood maltreatment in male and female treatment-seeking pathological gamblers. *Psychol Addict Behav* 2005; 19(2):226-9.

Notes: CORPORATE NAME: The Women's Problem Gambling Research Center  
Abstract: Little empirical research has evaluated childhood abuse in pathological gamblers. This study describes results of an analysis of childhood maltreatment histories among 149 pathological gamblers being treated at 1 of 7 gambling treatment programs. Measurements included instruments assessing gambling behavior and the Childhood Trauma Questionnaire (CTQ; D. P. Bernstein *et al.*, 1994). Women scored higher than men on the overall CTQ scale and subscales measuring childhood physical neglect, emotional abuse, and sexual abuse. Severity of childhood maltreatment was significantly and independently associated with lower age of onset of gambling and increased severity of gambling problems. This study suggests that childhood maltreatment is prevalent in pathological gamblers, especially female gamblers. These results warrant further investigation of

the role of childhood maltreatment in the etiology of pathological gambling and its treatment.

Petticrew M. Systematic reviews from astronomy to zoology: myths and misconceptions. *BMJ* 2001; 322(7278):98-101.

Peychl I. [Shaken baby syndrome]. *Cas Lek Cesk* 2005; 144(3):185-7; discussion 188-9. Abstract: Shaken baby syndrome represents a specific form of the Abused child syndrome. Injury usually concerns the baby's head and the brain and it is caused by thoughtless treatment accompanied by harsh shaking movements of the head and neck. It can cause a contusion of the cervical spinal cord, a rupture of the bridging veins, intracranial bleeding and a brain tissue impairment either due to the direct axonal damage, or namely by hypoxic-ischaemic insult. The development of the lesion can be fatal, or it can result in permanent impairment of the motor system, in mental or sensory deficits. Occurrence of the syndrome in the Czech Republic is not known, foreign data give 25 cases per 100000 children below one year of age. Injured babies represent over 1% of those hospitalised at paediatric units of intensive care and more than 10% of the death rate at those departments. Proven abuse has forensic consequences: however, convictive evidence can be difficult to obtain. Article gives a concrete case of a boy with the diagnose Shaken baby syndrome.

Pezdek K, Morrow A, Blandon-Gitlin I *et al.* Detecting deception in children: event familiarity affects criterion-based content analysis ratings. *J Appl Psychol* 2004; 89(1):119-26. Abstract: Statement Validity Assessment (SVA) is a comprehensive credibility assessment system, with the Criterion-Based Content Analysis (CBCA) as a core component. Worldwide, the CBCA is reported to be the most widely used veracity assessment instrument. We tested and confirmed the hypothesis that CBCA scores are affected by event familiarity; descriptions of familiar events are more likely to be judged true than are descriptions of unfamiliar events. CBCA scores were applied to transcripts of 114 children who recalled a routine medical procedure (control) or a traumatic medical procedure that they had experienced one time (relatively unfamiliar) or multiple times (relatively familiar). CBCA scores were higher for children in the relatively familiar than the relatively unfamiliar condition, and CBCA scores were significantly correlated with age. Results raise serious questions regarding the forensic suitability of the CBCA for assessing the veracity of children's accounts.

Pfefferbaum B, Doughty DE, Reddy C *et al.* Exposure and peritraumatic response as predictors of posttraumatic stress in children following the 1995 Oklahoma City bombing. *J Urban Health* 2002; 79(3):354-63. Abstract: Studies have demonstrated a positive

relationship between exposure and posttraumatic stress, but one's subjective appraisal of danger and threat at the time of exposure may be a better predictor of posttraumatic stress than more objective measures of exposure. We examined the role of peritraumatic response in posttraumatic stress reactions in over 2,000 middle school children 7 weeks after the 1995 Oklahoma City, Oklahoma, bombing. While many children reported hearing and feeling the blast and knowing direct victims, most were in school at the time of the explosion and therefore were not in direct physical proximity to the incident. Physical, interpersonal, and television exposure accounted for 12% of the total variance in our measure of posttraumatic stress when peritraumatic response was ignored. Peritraumatic response and television exposure accounted for 25% of the total variance, and physical and interpersonal exposure were not significant in this context. These findings suggest the importance of peritraumatic response in children's reactions to terrorism. These early responses can be used to help determine which children may experience difficulty over time.

Phillips M. Joan of Arc meets Mary Poppins: maternal re-nurturing approaches with male patients in Ego-State Therapy. *Am J Clin Hypn* 2004; 47(1):3-12. Abstract: Many patients with posttraumatic fragmentation demonstrate a positive response to the corrective possibilities provided through Ego-State Therapy. However, full resolution of presenting symptoms may not occur for individuals with significant childhood histories of parental abuse and neglect without opposite sex, as well as same sex, re-nurturing interventions. This presentation emphasizes the use of maternal re-nurturing methods with men who struggle with the effects of significant attachment deficits in early life. Case examples feature male patients with long-term difficulties in their adult relationships with women that had proved refractory to other therapy methods. Following Ego-State Therapy interventions with maternal symbolic figures, however, these problems improved dramatically. Therapeutic implications for cross-gender re-nurturing with patients who report different types of maternal attachment trauma are explored and discussed.

Piaggio G, Carroli G, Villar J *et al.* Methodological considerations on the design and analysis of an equivalence stratified cluster randomization trial. *Stat Med* 2001; 20(3):401-16. Notes: CORPORATE NAME: WHO Antenatal Care Trial Research Group Abstract: The World Health Organization and collaborating institutions in four developing countries have conducted a multi-centre randomized controlled trial, in which clinics were allocated at random to two antenatal care (ANC) models. These were the standard 'Western' ANC model and a 'new' ANC model consisting of tests, clinical procedures and follow-up

actions scientifically demonstrated to be effective in improving maternal and newborn outcomes. The two models were compared using the equivalence approach. This paper discusses the implications of the equivalence approach in the sample size calculation, analysis and interpretation of results of this cluster randomized trial. It reviews the ethical aspects regarding informed consent, concluding that the Zelen design has a place in cluster randomization trials. It describes the estimation of the intracluster correlation coefficient (ICC) in a stratified cluster randomized trial using two methods and reports estimates of the ICC obtained for many maternal, newborn and perinatal outcomes. Finally, it discusses analytical problems that arose: issues encountered using a composite index, heterogeneity of the intervention effect across sites, the choice of the method of analysis and the importance of efficacy analyses. The choice of the clustered Woolf estimator and the generalized estimating equations (GEE) as the methods of analysis applied is discussed.

Piccolo D, Ferrari A, Peris K, Diadone R, Ruggeri B, Chimenti S. Dermoscopic diagnosis by a trained clinician vs. a clinician with minimal dermoscopy training vs. computer-aided diagnosis of 341 pigmented skin lesions: a comparative study. *Br J Dermatol* 2002; 147(3):481-6. Abstract: **BACKGROUND:** In the last few years digital dermoscopy has been introduced as an additional tool to improve the clinical diagnosis of pigmented skin lesions. **OBJECTIVE:** To evaluate the validity of digital dermoscopy by comparing the diagnoses of a dermatologist experienced in dermoscopy (5 years of experience) with those of a clinician with minimal training in this field, and then comparing these results with those obtained using computer-aided diagnoses. **METHODS:** Three hundred and forty-one pigmented melanocytic and non-melanocytic skin lesions were included. All lesions were surgically excised and histopathologically examined. Digital dermoscopic images of all lesions were framed and analysed using software based on a trained artificial neural network. Cohen's kappa statistic was calculated to assess the validity with regard to the correct diagnoses of melanoma and non-melanoma. **RESULTS:** Sensitivity was high for the experienced dermatologist and the computer (92%) and lower for the inexperienced clinician (69%). Specificity of the diagnosis by the experienced dermatologist was higher (99%) than that of the inexperienced clinician (94%) and the computer assessment (74%). Notably, computer analysis gave a higher number of false positives (26%) compared with the experienced dermatologist (0.6%) and the inexperienced clinician (5.5%). **CONCLUSIONS:** Our results indicate that analysis either by a trained dermatologist or an artificial neural network-trained computer can improve the diagnostic accuracy of melanoma compared with that of an inexperienced clinician and that the computer diagnosis might represent a useful tool for the

screening of melanoma, particularly at centres not experienced in dermoscopy.

Pierce JP, Distefan JM, Jackson C, White MM, Gilpin EA. Does tobacco marketing undermine the influence of recommended parenting in discouraging adolescents from smoking? *Am J Prev Med* 2002; 23(2):73-81. Abstract: **OBJECTIVE:** The tobacco industry contends that parenting practices, not marketing practices, are critical to youth smoking. Our objective was to examine whether tobacco-industry marketing practices undermine the protective effect of recommended authoritative parenting against adolescent smoking. **DESIGN AND SETTING:** Receptivity to tobacco advertising and promotions was assessed in 1996 from a representative sample of California adolescent never-smokers aged 12 to 14 years. A follow-up survey of 1641 of these adolescents was conducted in 1999 that included measures of the key components of authoritative parenting: parental responsiveness, monitoring, and limit setting. **MAIN OUTCOME MEASURE:** Smoking initiation in adolescents. **RESULTS:** Adolescents in families with more-authoritative parents were half as likely to smoke by follow-up as adolescents in families with less-authoritative parents (20% vs 41%,  $p < 0.0001$ ). In families with more-authoritative parents, adolescents who were highly receptive to tobacco-industry advertising and promotions were significantly more likely to smoke (odds ratio=3.52, 95% confidence interval =1.10-11.23), compared to those who were minimally receptive. This effect was not significant in adolescents in families with less-authoritative parents. The overall attributable risk (adjusted for exposure to peer smokers) of smoking from tobacco-industry advertising and promotions was 25%. However, an estimated 40% of adolescent smoking in families with more-authoritative parents was attributable to tobacco-industry advertising and promotions; this was five times the attributable risk seen in families with less-authoritative parents (8%). **CONCLUSION:** The promotion of smoking by the tobacco industry appears to undermine the capability of authoritative parenting to prevent adolescents from starting to smoke.

Pierce R. Thoughts on interpersonal violence and lessons learned: fact or fiction. *J Interpers Violence* 2005; 20(1):43-50.

Abstract: Although interpersonal violence is evident in all strata of society, every geographical area in the country, and across each gender, it takes courage to acknowledge our passivity about the phenomena, particularly when people of color are involved. Thus, the mass incarcerations of African American men and women and data citing the overrepresentation of African American children not being adequately served in the child welfare system are highlighted to address the three questions posed to authors: What have we learned about violence and trauma over two decades? What should be learned over the next 10 years about

violence and trauma? What methodologies exist that show promise of affecting a better understanding of violence and trauma?

Pilowsky DJ, Zybert PA, Hsieh PW, Vlahov D, Susser E. Children of HIV-positive drug-using parents. *J Am Acad Child Adolesc Psychiatry* 2003; 42(8):950-6. Abstract: OBJECTIVE: Associations between human immunodeficiency virus (HIV) status of injection drug users (IDUs) and their children's psychopathology and social functioning were examined. METHOD: Parents (N = 61) were drawn from an ongoing longitudinal study of inner city, primarily African-American IDUs. Children (N = 79) were 6 to 11 years of age, currently living with the IDU parent. Parental variables included HIV status, apparent and inapparent HIV infection (with HIV-related medical symptoms and/or disclosure of parental HIV status to children; with neither medical symptoms nor disclosure, respectively), presence of HIV-related medical symptoms, HIV disclosure status to each child, and depression as ascertained by the Center for Epidemiologic Studies-Depression. Children's outcomes (competencies, psychiatric symptoms, and disorders) were assessed with the Child Behavior Checklist and the Schedule for Affective Disorders and Schizophrenia for School-Age Children. RESULTS: Children of IDU parents exhibited high rates of psychopathology. Parental HIV infection per se had no discernible impact on children's outcomes. The apparent HIV infection of a parent was associated with an eightfold increase (odds ratio 7.80; 95% confidence interval 1.56-39.09) in the prevalence of disruptive behavior disorders (compared with children of HIV-negative parents). Parental depression was associated with a threefold increase in the prevalence of children's disruptive behavior disorders (odds ratio 3.49, 95% confidence interval 1.11-11.04). CONCLUSIONS: Parental HIV status per se does not seem to have a differential impact on the affected children. The apparent HIV infection of a parent may be associated with children's externalizing symptoms and disorders.

Pilowsky DJ, Zybert PA, Vlahov D. Resilient children of injection drug users. *J Am Acad Child Adolesc Psychiatry* 2004; 43(11):1372-9. Abstract: OBJECTIVE: To examine associations between resilience in children of injection drug users and children's coping strategies, parenting stress, and children's social support. METHOD: Injection drug-using parents (n=91) and their children aged 6 to 11 (n=117) were recruited in Baltimore (1997-1999). Resilience was defined as scoring in the lowest quartile of the Child Behavior Checklist total psychopathology score. Coping strategies used by resilient and nonresilient children, the extent and types of social support that they received, and the level of parenting stress reported by their parents were compared and contrasted. RESULTS: Rates of depressive, anxiety, and disruptive behavior disorders were 15.4%, 22.2%, and 21.4%, respectively, for the entire sample.

Compared with the nonresilient, resilient children were less likely to use two avoidance coping strategies (internalizing [p=.002] and externalizing [p=.017]). The level of actual support received by resilient and nonresilient children did not differ significantly (p=.202). Perceived support was greater among resilient children (as reported by their parents; p <.001), and their parents reported lower parenting stress (p=.042). CONCLUSIONS: A significant proportion of children of injection drug users are in need of clinical care. Interventions to help children of substance-abusing parents modify their coping style merit exploration.

Pimlott-Kubiak S, Cortina LM. Gender, victimization, and outcomes: reconceptualizing risk. *J Consult Clin Psychol* 2003; 71(3):528-39. Abstract: Large-scale studies of gender differences in psychopathological reactions to victimization have focused on posttraumatic stress disorder, overlooking other trauma-related disorders. The present study expands this literature with a contextualized examination of interpersonal aggression exposure and sequelae. Using k-means cluster analysis on a sample of 16,000, the authors identified 8 distinct profiles of exposure to sexual violence, physical assault, stalking, and emotional abuse. Analyses of covariance then suggested links among victimization profile, gender, and mental and physical health. Results revealed no meaningful interactive effects of gender and interpersonal aggression on outcomes, once lifetime exposure to aggressive events was adequately taken into account. These findings argue against theories of female victims' greater vulnerability to pathological outcomes, instead linking risk to exposure history.

Pinosa C, Marchand C, Tubiana-Rufi N, Gagnayre R, Albano MG, D'Ivernois JF. The use of concept mapping to enlighten the knowledge networks of diabetic children: a pilot study. *Diabetes Metab* 2004; 30(6):527-34.

Abstract: OBJECTIVE: The value of concept mapping in enlightening nature and organization of knowledge was shown with adult diabetic or obese patients. Our objectives were to ascertain the relevance and feasibility of concept mapping in diabetic children during an educational program. METHOD: This qualitative research was performed in 5 children from 8 to 13 years. Concept maps were drawn at the beginning (Phase 1) and at the end (Phase 2) of an educational program. During the interview each child was invited to express himself starting from the central concept: "diabetes", and to express his/her knowledge, representations, and life experience. RESULTS: The ten maps analysis shows: an increase of knowledge between phase 1 and phase 2 (+34%), towards a deepening of initial knowledge and an addition of new knowledge (43% and 41% of the added knowledge); a decrease of inaccurate knowledge in phase 2; an enrichment of the knowledge networks (+16 cross

links); an increase of knowledge related to the ways to behave knowledge (+42%). CONCLUSION: This preliminary report demonstrated that concept maps were feasible, useful and relevant in therapeutic education of children. This method allowed us to show how every child connected his knowledge and how it was modified by an educational intervention. Concept maps therefore contributed to individual educational diagnosis and assessment of new knowledge integration.

Pirila-Parkkinen K, Pirttiniemi P, Alvesalo L, Silven O, Heikkilä J, Osborne RH. The relationship of handedness to asymmetry in the occlusal morphology of first permanent molars. *Eur J Morphol* 2001; 39(2):81-9.

Abstract: Handedness has been shown to be related to a number of systematic asymmetries in body dimensions, dermatoglyphic patterns and cerebral morphology. The aim here was to compare linear and angular tooth crown asymmetries of the permanent molars in healthy right-handed and left-handed subjects. The material comprised 27 children with recorded concordant left-side dominance of hand, eye and foot. The controls were an age- and sex-matched group with right side dominance. The material is based on the Collaborative Perinatal Project where detailed medical records and the dentitions, including accurate dental impressions, of over two thousand American children were examined in the USA in the sixties. Machine vision technique was used to obtain accurate three-dimensional information from the occlusal surfaces of the first permanent upper and lower molars. The directional asymmetry values of angular measurements of mandibular first molars showed evidence of asymmetry of opposite direction between the two examined groups. The results indicate that occlusal morphology of first permanent molars may be affected by handedness, and this tendency is most evident in the angular measurements of the mandibular molars. Fluctuating asymmetry did not differ significantly between the examined groups.

Pitche P, Kombate K, Gbadoe AD, Tchangai-Walla K. [Anogenital warts in young children in hospital consultation in Lome (Togo). Role of transmission by sexual abuse]. *Med Trop (Mars)* 2001; 61(2):158-62. Abstract: The purpose of this 20-month prospective study conducted in the dermatology department of Lome Teaching Hospital was to determine the prevalence of sexual abuse in pre-adolescent children with anogenital warts. From May 1997 to December 1998, a total of 16 cases of anogenital warts were diagnosed in children under the age of 12 years. Sexual abuse was discovered in 8 cases. All 8 cases involved girls (mean age, 6.1 +/- 1.9 years). The mode of acquisition involved self-infection from non anogenital warts in three cases and contamination by the mother in three cases. In two cases the mode of acquisition could not be identified. The alleged abuser was a member of

child's family in 3 cases, a household employee working at the child's home in three cases, a teacher in 1, and a neighbor in 1. Syphilitic tests were negative in all children. However HIV infection was detected and the contaminator was identified in one 10-year-old girl. The results of this study document the correlation between anogenital warts and sexual abuse. In Black Africa, the consequences of child sexual abuse, which is not uncommon especially in major cities, are aggravated by the high prevalence of HIV infection.

Pittman T. Significance of a subdural hematoma in a child with external hydrocephalus. *Pediatr Neurosurg* 2003; 39(2):57-9.

Pivarcsi A, Homey B. Chemokine networks in atopic dermatitis: traffic signals of disease. *Curr Allergy Asthma Rep* 2005; 5(4):284-90. Abstract: Atopic dermatitis is a chronic or chronically relapsing inflammatory skin disease with a prevalence ranging from 10% to 20% in children and 1% to 3% in adults of developed countries. Skin-infiltrating leukocytes play a pivotal role in the initiation and amplification of atopic skin inflammation. Recent studies demonstrated that infiltration of inflammatory cells into tissues is regulated by chemokines. A subset of chemokines including CCL27, CCL17, CCL22, CCL18, CCL11, and CCL13 are highly expressed in atopic dermatitis. The corresponding chemokine receptors are found on the main leukocyte subsets involved in allergic skin inflammation, such as T cells, eosinophils, and dendritic cells. In this article, we provide an overview of the role of chemokines in the complex immunopathogenesis of atopic dermatitis, highlighting potential areas for therapeutic intervention.

Pizzi NJ. Bleeding predisposition assessments in tonsillectomy/adenoidectomy patients using fuzzy interquartile encoded neural networks. *Artif Intell Med* 2001; 21(1-3):65-90. Abstract: A fuzzy set theoretic methodology is described that serves as a classification preprocessing strategy for supervised feed-forward neural networks. This methodology, fuzzy interquartile encoding, determines the respective degrees to which a feature belongs to a collection of fuzzy sets that overlap at the respective quartile boundaries of the feature. These membership values are subsequently used in place of the original feature. This transformation has a normalizing effect on the feature space and is more robust to feature outliers. Its effectiveness is scrutinized using several synthetic data sets with various underlying distributions. Fuzzy interquartile encoding is shown to consistently improve the discriminatory power of the underlying classifiers. The methodology is also applied to two biomedical data sets relating to tonsillectomy and/or adenoidectomy patients who may or may not have had a predisposition

to excessive bleeding during their operation. The features of the first data set are blood sample test results acquired from a coagulation laboratory and the class labels are one of three hemostatic defects as identified by the reference tests. The second data set consists of patient responses to queries from a bleeding tendency questionnaire. Normal and abnormal class labels were derived from a hematology expert system designed in consultation with a pediatric hematologist. Fuzzy interquartile encoding effected an 11% improvement in the classification accuracy of the underlying neural network classifier with the former data set and 18% with the latter.

Place I, Englert Y. A prospective longitudinal study of the physical, psychomotor, and intellectual development of singleton children up to 5 years who were conceived by intracytoplasmic sperm injection compared with children conceived spontaneously and by in vitro fertilization. *Fertil Steril* 2003; 80(6):1388-97. Abstract: **OBJECTIVE:** To assess the somatic, psychomotor, and intellectual development of children conceived through intracytoplasmic single sperm injection (ICSI) over the whole preschool period. **DESIGN:** Prospective, controlled, cohort study. **SETTING:** Fertility clinic in Brussels, Belgium. **PATIENT(S):** Sixty-six ICSI-conceived children prospectively compared with 52 IVF-conceived and 59 spontaneously conceived children. All children were full-term singletons. **INTERVENTION(S):** Home visits by a trained psychologist. Standardized interviews. Assessments using the revised Brunet-Lezine scale and the revised Wechsler preschool and primary scale of intelligence. **MAIN OUTCOME MEASURE(S):** Physical growth and general health. Formal developmental and intellectual assessments. **RESULT(S):** Children conceived by ICSI were healthy: no significant differences appeared in the incidence of combined congenital malformations (11.3%), health problems (44.1%), surgical interventions (18.6%), and hospitalizations (6.8%), nor for the developmental assessments (mean developmental quotient at 9 months: 93.9; at 18 months: 102.0). For the intellectual assessments, the between-group differences disappeared when adjusted for levels of parental education (mean intelligence quotient at 3 years: 97.0; at 5 years: 103.3). **CONCLUSION(S):** This pilot study shows that throughout the preschool period, ICSI-conceived children have psychomotor and intellectual development similar to that of IVF-conceived and spontaneously conceived children. These conclusions need to be confirmed by multicenter studies.

Place MD. Three harsh new realities. *Health Prog* 2002; 83(5):6-8.

Plain LC. Activism in an age of restraint: the resiliency of administrative structure in implementing the State

Children's Health Insurance Program. *J Health Hum Serv Adm* 2004; 27(2):210-39. Abstract: This article examines state efforts to build administrative structures and outreach networks in the State Children's Health Insurance Program (CHIP) through a comparative review of 18 states that have been the subject of ongoing research by the Nelson A. Rockefeller Institute of Government. The article explores the role that institutional structures play at the state level in shaping the implementation and administration of federal policy choices. States have generally opted to rely largely on existing Medicaid bureaucracies in order to implement the new CHIP programs. As a result, CHIP programs have been tightly integrated into existing Medicaid structures. Rarely put forward as exemplars of responsiveness and, these bureaucracies have nonetheless played a crucial role in building and managing CHIP programs across the United States. As this analysis will show, this has even been the case in those few states that have opted to officially house CHIP administration outside of the Medicaid bureaucracy. Furthermore, existing Medicaid systems have often been active as partners and participants in efforts to publicize and promote the CHIP program through outreach and education efforts. As part of these initiatives, efforts have been made to portray CHIP as a form of health insurance rather than a welfare benefit. A slight paradox results where key actors in the health and human services bureaucracy play an active role in program management while making efforts to disassociate the program from the traditional welfare system. These efforts have been largely successful. And in doing so, not only have children been brought into the CHIP program but more families have been connected to the Medicaid program. In short, a review of state experiences reveals the resiliency and flexibility of existing state administrative systems in responding to and addressing substantive policy change.

Plews C, Bryar R, Closs J. Clients' perceptions of support received from health visitors during home visits. *J Clin Nurs* 2005; 14(7):789-97. Abstract: **AIMS AND OBJECTIVES:** The current study sought to identify how many mothers from 149 visits carried out by seven health visitors identified support as a feature of the visit, whether this type of support was unique to the health visitor and what support meant to them. These responses were then compared with the taxonomies of social support from the social support literature. **BACKGROUND:** Some studies of client perceptions describe support as an element of home visits by health visitors. However, the importance, relevance and impact on the client of this support are not described in detail. Social support theory suggests that there are tangible benefits to people's well-being and their ability to cope with various challenges that may arise from individuals' perceptions of receiving support. **DESIGN:** Qualitative study using semistructured interviews. **METHODS:**

Seven volunteer health visitors recruited 149 women into the study. These clients were interviewed by the researcher, usually within one week of the home visit by their health visitor. The discussions were audio-taped and the resulting transcripts analysed using content analysis. FINDINGS: Thirty-seven women identified receiving support which they said was only available from the health visitor. The relevance of this support to the mother and the impact on her well-being varied within the group suggesting differing perceptions of support by clients according to their personal situation. There was a correspondence between the descriptions of support given by the women and the taxonomies of social support from the social support literature. CONCLUSION: For some interactions between clients and their health visitors the existing theory of social support may provide an explanation of how health visitors contribute to clients' perceived ability to cope and well-being. RELEVANCE TO CLINICAL PRACTICE: Social support may be defined as a possible outcome of health visiting. This concept will have use within educational programmes to demonstrate to students how health visiting can have an impact on clients' well-being. Similarly, the concept could be used to investigate and record health visiting practice.

Pliszka SR. Psychiatric comorbidities in children with attention deficit hyperactivity disorder: implications for management. *Paediatr Drugs* 2003; 5(11):741-50. Abstract: Attention deficit hyperactivity disorder (ADHD) is frequently comorbid with a variety of psychiatric disorders. These include oppositional defiant disorder and conduct disorder (CD), as well as affective, anxiety, and tic disorders. ADHD and CD with comorbid CD appear to be distinct subtypes; children with ADHD/CD are at higher risk of antisocial personality and substance abuse as adults. Stimulants are often effective treatments for aggressive or antisocial behavior in patients with ADHD, but mood stabilizers or atypical antipsychotics may be used to treat explosive aggressive outbursts. Response to stimulants is not affected by comorbid anxiety, but children with ADHD/anxiety disorder may show greater benefit from psychosocial interventions than those with ADHD alone. The degree of prevalence of major depressive disorder (MDD) and bipolar disorder among children with ADHD is controversial, but a subgroup of severely emotionally labile ADHD children who present serious management issues for the clinician clearly exists. Antidepressants may be used in conjunction with stimulants to treat MDD, while mood stabilizers and atypical antipsychotics are often required to treat manic symptoms or aggression. After resolution of the manic episode, stimulant treatment of the comorbid ADHD may be safely undertaken. Recent research suggests that stimulants can be safely used in children with comorbid ADHD and tic disorders, but the addition of anti-tic agents to stimulants is often necessary. Clinicians who work

with patients with ADHD should be prepared to deal with a wide range of emotional and behavioral problems beyond the core symptoms of inattention and impulsivity/hyperactivity.

Pliszka SR, Lopez M, Crismon ML *et al.* A feasibility study of the children's medication algorithm project (CMAP) algorithm for the treatment of ADHD. *J Am Acad Child Adolesc Psychiatry* 2003; 42(3):279-87. Abstract: OBJECTIVE: To determine whether an algorithm for the treatment of attention-deficit/hyperactivity disorder (ADHD) can be implemented in a community mental health center. METHOD: Fifty child and adolescent patients at Texas community mental health centers who met criteria for ADHD were treated according to an algorithm-based disease management program for ADHD. Psychiatrists were trained in the use of the algorithm, and each subject underwent a baseline assessment consisting of a structured interview and standardized rating scales. Subjects were monitored for 4 months. At the end of treatment, the psychiatrists completed the Clinical Global Impression Scale (CGI) and the baseline rating scales were repeated. The primary variables of interest were psychiatrist and family adherence to the algorithm. To examine impact on treatment outcome, the CGI of the algorithm subjects was compared with CGIs based on chart reviews of 118 historical controls. RESULTS: Psychiatrists implemented the major aspects of the algorithm, but the detailed tactics of the algorithm (use of fixed titration of stimulants) were less well adhered to. CONCLUSIONS: An algorithm for the treatment of ADHD can be implemented in a community mental health center.

Pollack-Nelson C, Drago DA. Supervision of children aged two through six years. *Inj Control Saf Promot* 2002; 9(2):121-6.

Abstract: Manufacturers of household products--including appliances, exercise equipment, and even some children's toys--expect consumers to supervise their children to prevent product-related injuries. This approach to hazard prevention places the burden of safety on parents and caretakers. This study examined actual supervision practices of parents of children between the ages of two and six years. 59 parents, aged 31 to 40 years, residing in Montgomery County, Maryland, completed a 24-item self-administered questionnaire, consisting of multiple choice and open-ended questions. Nearly all respondents reported that there are times when their children are in a different room from them. When the children are out of sight, parents reported checking on their children periodically, with increasingly longer periods between observations, as the child gets older. Nearly half of the children got out of bed in the morning always or often before a parent. Ninety-five percent of parents perceived that their child was at no risk or slight risk of injury when getting up in the morning before them. In conclusion, it can be said that many parents supervise

their children by being close-by and on-hand as needed, rather than being directly involved in the child's activities. Manufacturers are encouraged to employ passive measures and sound designs, rather than rely on close parental supervision for injury prevention.

Pollak SD. Experience-dependent affective learning and risk for psychopathology in children. *Ann N Y Acad Sci* 2003; 1008:102-11.

Abstract: The influence of childhood affective experiences across development may be understood in terms of preparedness to learn about emotion, combined with general immaturity and neuro-plasticity of perceptual systems. Early in development, processing resources are relatively immature and limited in capacity, thereby constraining how much information the young child can absorb. But it is clear that learning about emotions proceeds swiftly in nearly all children, suggesting biological preparedness to track associations between certain stimuli and outcomes. It is proposed here that limited processing capacity, in tandem with dispositions to filter or select key privileged stimuli in the environment, facilitates adaptive, rapid, affective learning. The developmental organization of affective systems is contingent upon those features of input that are most learnable, such as signals that are particularly salient, frequent, or predictable. Therefore, plasticity confers risk for maladaptation in that children's learning will be based upon these prominent features of the environment, however aberrant.

Pollak SD, Kistler DJ. Early experience is associated with the development of categorical representations for facial expressions of emotion. *Proc Natl Acad Sci U S A* 2002; 99(13):9072-6.

Abstract: A fundamental issue in human development concerns how the young infant's ability to recognize emotional signals is acquired through both biological programming and learning factors. This issue is extremely difficult to investigate because of the variety of sensory experiences to which humans are exposed immediately after birth. We examined the effects of emotional experience on emotion recognition by studying abused children, whose experiences violated cultural standards of care. We found that the aberrant social experience of abuse was associated with a change in children's perceptual preferences and also altered the discriminative abilities that influence how children categorize angry facial expressions. This study suggests that affective experiences can influence perceptual representations of basic emotions.

Pollak SD, Tolley-Schell SA. Selective attention to facial emotion in physically abused children. *J Abnorm Psychol* 2003; 112(3):323-38.

Abstract: The ability to allocate attention to emotional cues in the environment is an important feature of

adaptive self-regulation. Existing data suggest that physically abused children overattend to angry expressions, but the attentional mechanisms underlying such behavior are unknown. The authors tested 8-11-year-old physically abused children to determine whether they displayed specific information-processing problems in a selective attention paradigm using emotional faces as cues. Physically abused children demonstrated delayed disengagement when angry faces served as invalid cues. Abused children also demonstrated increased attentional benefits on valid angry trials. Results are discussed in terms of the influence of early adverse experience on children's selective attention to threat-related signals as a mechanism in the development of psychopathology.

Pollock L. Discrimination and prejudice: Muslim women's experiences of maternity care. *RCM Midwives* 2005; 8(2):55.

Pollock L. Maternity leave challenge to students' rights. *RCM Midwives* 2003; 6(7):284-5.

Pollock TR, Franklin C. Use of evidence-based practice in the neonatal intensive care unit. *Crit Care Nurs Clin North Am* 2004; 16(2):243-8.

Abstract: The process change described is an ongoing project in the HICN. Through this process we found that developmentally sensitive care can be accomplished as early as the time of birth by minimizing trauma to ELBW infants, keeping them nested with minimal handling. This also supports the goal for this population of minimizing cold stress and its effects. Gentle ventilation can be achieved in the delivery room by understanding physiology and the effects of ventilation on the ELBW lung tissue.

Pomery EA, Gibbons FX, Gerrard M, Cleveland MJ, Brody GH, Wills TA. Families and risk: prospective analyses of familial and social influences on adolescent substance use. *J Fam Psychol* 2005; 19(4):560-70.  
Abstract: Parental, peer, and older siblings' contributions to adolescents' substance use were investigated with 2 waves of panel data from 225 African American families. Structural equation modeling showed that older siblings' behavioral willingness (BW) to use substances at Time 1 (T1) predicted target adolescents' Time 2 (T2) use, controlling for other T1 variables. Regression analyses revealed an interaction between targets' and siblings' BW, such that targets were more likely to use at T2 if both they and their siblings reported BW at T1. This interaction was stronger for families living in high-risk

neighborhoods. Finally, siblings' willingness buffered the impact of peer use on targets' later use: Low sibling BW was associated with less evidence of peer influence.

Poole CA, Brookes NH, Clover GM. Confocal imaging of the human keratocyte network using the vital dye 5-chloromethylfluorescein diacetate. *Clin Experiment Ophthalmol* 2003; 31(2):147-54. Abstract: BACKGROUND: The human corneal stroma consists of intercalated layers of collagen and keratocytes. These cells are known to maintain the stroma and aid in repair but it is likely they have other crucial roles throughout the cornea. The complexity of their anatomy is revealed in this study by ex vivo in situ images of the human keratocyte covering a range of ages. METHODS: Human donor corneas of different ages were stained with 5-chloromethylfluorescein diacetate (CMFDA), a dye that is anchored and retained within the cell cytoplasm. The tissue was fixed, sectioned, mounted, and then imaged using a confocal laser scanning microscope at various magnifications and tissue planes. The digital image sets were transferred to multifunction image processing software for analysis and production of 3-D stereo images of keratocyte networks throughout the stroma. RESULTS: High quality images of CMFDA-stained cells revealed differences in the structure and orientation of keratocytes in the anterior, central and posterior stroma, which did not differ throughout the age-range studied. This method reveals very fine cell process ramifications not previously visualized, orientated in lateral and antero-posterior directions, and it confirms the potential for multidirectional communication between keratocyte networks. CONCLUSIONS: This qualitative study found consistency of keratocyte morphology in the normal human cornea throughout life. It confirmed differences in keratocyte anatomy, and the potential for rapid cellular communication by multiple interconnecting processes supporting cohesive keratocyte activity. This high-resolution 3-D microscopic study should assist in identifying gross deviant cellular behaviour in post-surgical and disease states.

Popp J, Douglas-England K, Casebeer A, Tough SC. Creating frameworks for providing services closer to home in the context of a network. *Healthc Manage Forum* 2005; 18(2):27-33. Abstract: Networks can be used to develop shared frameworks that extend limited specialized healthcare services beyond tertiary level settings to provide services closer to home. This article provides an overview of networks, describes the context and purpose of the Southern Alberta Child & Youth Health Network, reports on early experiences with implementation of an Outreach Services Framework, and discusses implications from a network perspective.

Porjesz B, Almasy L, Edenberg HJ *et al.* Linkage disequilibrium between the beta frequency of the human EEG and a GABAA receptor gene locus. *Proc Natl Acad Sci U S A* 2002; 99(6):3729-33. Abstract: Human brain oscillations represent important features of information processing and are highly heritable. A common feature of beta oscillations (13-28 Hz) is the critical involvement of networks of inhibitory interneurons as pacemakers, gated by gamma-aminobutyric acid type A (GABA(A)) action. Advances in molecular and statistical genetics permit examination of quantitative traits such as the beta frequency of the human electroencephalogram in conjunction with DNA markers. We report a significant linkage and linkage disequilibrium between beta frequency and a set of GABA(A) receptor genes. Uncovering the genes influencing brain oscillations provides a better understanding of the neural function involved in information processing.

Porter LS, Porter BO. A blended infant massage--parenting enhancement program for recovering substance-abusing mothers. *Pediatr Nurs* 2004; 30(5):363-72, 401.

Abstract: Interventions that build upon the natural components of early mother-infant interactions are critical to reversing the sequelae of maternal substance abuse and breaking the cycle of addiction. This paper proposes a theoretical model that blends infant massage (IM) into a planned parenting enhancement program (PEP) to promote improved health outcomes in recovering substance-abusing mothers (SAMs) and their babies. With 4.6 million women of child-bearing age regularly using cocaine in the United States and 750,000 drug-exposed births annually, maternal substance abuse highlights the multigenerational impact of drug use in high-risk populations and its risks to our children. The proposed IMPEP model provides a means to assist recovering SAMs in making cognitive-behavioral changes through new knowledge about parenting and parenting skills, with a special focus on infant stimulation via massage. The goal is to enable recovering SAMs to become confident and responsive mothers, empowering them to become effective parents. Pilot data suggest the Infant Massage Parenting Enhancement Program (IMPEP) is effective for both mother and infant, and merits a controlled systematic study.

Portwood SG, Dodgen DW. Influencing policymaking for maltreated children and their families. *J Clin Child Adolesc Psychol* 2005; 34(4):628-37. Abstract: Public policy can be a powerful tool for children and their families. Accordingly, this article addresses how psychologists and other child-oriented researchers can leverage this tool to ensure that child and family issues, specifically issues related to child abuse and neglect, receive adequate attention. We encourage a bidirectional relationship between policymakers and experts in child maltreatment

through which policymakers solicit and employ relevant expertise, and psychologists, in turn, provide useful information to policymakers. To facilitate such relationships, this article offers practical guidance to psychologists on understanding the policymaking process, gaining familiarity with relevant policy, communicating effectively with policymakers, and understanding the unique contributions that psychologists can make to the policy process.

Posner MI, Rothbart MK. Influencing brain networks: implications for education. *Trends Cogn Sci* 2005; 9(3):99-103.

Abstract: In our view, a central issue in relating brain development to education is whether classroom interventions can alter neural networks related to cognition in ways that generalize beyond the specific domain of instruction. This issue depends upon understanding how neural networks develop under the influence of genes and experience. Imaging studies have revealed common networks underlying many important tasks undertaken at school, such as reading and number skills, and we are beginning to learn how genes and experience work together to shape the development of these networks. The results obtained appear sufficient to propose research-based interventions that could prove useful in improving the ability of children to adjust to the school setting and to acquire skills like literacy and numeracy.

Potegal M, Archer J. Sex differences in childhood anger and aggression. *Child Adolesc Psychiatr Clin N Am* 2004; 13(3):513-28, vi-vii.

Abstract: There are few differences in the frequency or intensity of men's and women's self-reported or observed anger. Women are more likely to be angered by relationship conflicts than men. Men are more frequently the targets of anger than women. Typically, men see the expression of anger as exerting dominance, whereas women view it as a loss of control. There are also sex differences in the mode of anger expression. At ages 8 and older, girls are more likely to engage in "relational" aggression (eg, deliberate social ostracism). The most consistent and salient difference in anger expression is women's tendency to cry when angry, whereas men are more likely to throw things or hit. The difference in physical aggression appears in children who are as young as 1 to 2 years of age. Despite an overall reduction in physical aggression after 2 to 3 years of age, the sex difference remains consistent into adulthood. In contrast to differences in physical aggression, differences in anger are few and inconsistent up to 4 or 5 years of age. By this age, girls tend to suppress the expression of anger consciously. By about 7 to 8 years of age, adult like differences become more consistent, with boys expressing more anger.

Potter N. Differences in child rearing. Cultural contrasts:

bringing up children the Honduran way. *J Fam Health Care* 2005; 15(1):26-8.

Abstract: The author, a health visitor now living in Honduras, Central America, describes child-rearing practices in Honduras and contrasts them with those in the UK.

Pottinger AM. Children's experience of loss by parental migration in inner-city Jamaica. *Am J Orthopsychiatry* 2005; 75(4):485-96.

Abstract: Migratory separation, when parents migrate and leave their children behind, was investigated in a case-control sample of 9- to 10-year-olds living in inner-city communities in Kingston and St Andrew, Jamaica (N = 54). Data analyses using descriptive statistics and bivariate correlations showed that children's reactions to their parents' migration were directly related to poor school performance and psychological difficulties. Additionally, being currently exposed to violence in the home and/or community was significantly associated with high scores on a measure of grief intensity. "Protective" factors included having someone to talk to about the migration and living in a supportive family. Migratory separation needs detailed investigation like that devoted to other childhood family disruptions, such as parental divorce or death.

Powell C. 'Children are unbeatable' a nurse's perspective. *Paediatr Nurs* 2004; 16(8):29.

Powell DL, Stewart V. Children. The unwitting target of environmental injustices. *Pediatr Clin North Am* 2001; 48(5):1291-305.

Abstract: Children have little control over where they live, what they eat, the financial circumstances of their families, or the developmental activities and behaviors that make them vulnerable to environmental contaminants. Minority and poor families disproportionately live in communities with landfills, hazardous waste facilities, incinerators, industrial plants, and old housing with poor indoor air quality and lead-based paint. Residents of these communities are also more likely than are more affluent communities to consume fish on a regular basis from local waters, many of which have banned fishing. Consequently, these children and their families are exposed more frequently than are children in other communities to potentially dangerous chemicals that can affect health. Data indicate that poor and minority children have higher rates of asthma, elevated blood lead levels, learning disabilities, and hyperactivity than do non-minority and more affluent children. When a group of people is exposed unfairly and inequitably to toxins in their communities, workplaces, and schools, a

phenomenon called environmental discrimination or environmental racism exists. Environmental justice is a US governmental remedy that requires the application of fair strategies and processes in the resolution of inequality related to environmental contamination. The US response resulted in the establishment of offices of Environmental Justice within the EPA and ATSDR and passage of important legislation and policies, such as the Community Planning and Right-to-Know Act of 1986, Executive Order 12898 (Federal Actions to Address Environmental Justice in Minority Populations), and Executive Order 13045, a parallel order to protect low-income and minority children from actual and potential environmental hazards. Communities and advocacy groups play an important role in promoting healthier environments for children. Frequently, low-income and minority communities are perceived as less powerful, less organized, and ill equipped to defend against actual and potential sources of environmental contamination. Health care professionals are in a strategic position to assist with community development, organizing, and empowerment through educational programming, networking, and supporting other activities that bring attention to the plight of environmentally vulnerable communities.

Prange MT, Coats B, Duhaime AC, Margulies SS. Anthropomorphic simulations of falls, shakes, and inflicted impacts in infants. *J Neurosurg* 2003; 99(1):143-50.

Abstract: OBJECT: Rotational loading conditions have been shown to produce subdural hemorrhage and diffuse axonal injury. No experimental data are available with which to compare the rotational response of the head of an infant during accidental and inflicted head injuries. The authors sought to compare rotational deceleration sustained by the head among free falls, from different heights onto different surfaces, with those sustained during shaking and inflicted impact. METHODS: An anthropomorphic surrogate of a 1.5-month-old human infant was constructed and used to simulate falls from 0.3 m (1 ft), 0.9 m (3 ft), and 1.5 m (5 ft), as well as vigorous shaking and inflicted head impact. During falls, the surrogate experienced occipital contact against a concrete surface, carpet pad, or foam mattress. For shakes, investigators repeatedly shook the surrogate in an anteroposterior plane; inflicted impact was defined as the terminal portion of a vigorous shake, in which the surrogate's occiput made contact with a rigid or padded surface. Rotational velocity was recorded directly and the maximum (peak-peak) change in angular velocity ( $\Delta\theta(\max)$ ) and the peak angular acceleration ( $\theta(\max)$ ) were calculated. Analysis of variance revealed significant increases in the  $\Delta\theta(\max)$  and  $\theta(\max)$  associated with falls onto harder surfaces and from higher heights. During inflicted impacts against rigid surfaces, the  $\Delta\theta(\max)$  and  $\theta(\max)$  were significantly greater than those

measured under all other conditions. CONCLUSIONS: Vigorous shakes of this infant model produced rotational responses similar to those resulting from minor falls, but inflicted impacts produced responses that were significantly higher than even a 1.5-m fall onto concrete. Because larger accelerations are associated with an increasing likelihood of injury, the findings indicate that inflicted impacts against hard surfaces are more likely to be associated with inertial brain injuries than falls from a height less than 1.5 m or from shaking.

Prater CD, Zylstra RG. Autism: a medical primer. *Am Fam Physician* 2002; 66(9):1667-74. Abstract: Autistic disorder, a pervasive developmental disorder resulting in social, language, or sensorimotor deficits, occurs in approximately seven of 10,000 persons. Early detection and intervention significantly improve outcome, with about one third of autistic persons achieving some degree of independent living. Indications for developmental evaluation include no babbling, pointing, or use of other gestures by 12 months of age, no single words by 16 months of age, no two-word spontaneous phrases by 24 months of age, and loss of previously learned language or social skills at any age. The differential diagnosis includes other psychiatric and pervasive developmental disorders, deafness, and profound hearing loss. Autism is frequently associated with fragile X syndrome and tuberous sclerosis, and may be caused by lead poisoning and metabolic disorders. Common comorbidities include mental retardation, seizure disorder, and psychiatric disorders such as depression and anxiety. Behavior modification programs are helpful and are usually administered by multidisciplinary teams, targeted medication is used to address behavior concerns. Many different treatment approaches can be used, some of which are unproven and have little scientific support. Parents may be encouraged to investigate national resources and local support networks.

Pratt HD, Greydanus DE. Violence: concepts of its impact on children and youth. *Pediatr Clin North Am* 2003; 50(5):963-1003.

Abstract: Although nations continue to remain involved in ongoing armed conflicts, the threat of direct exposure to violence for American children and youth is more likely to be from the interpersonal violence that occurs in homes, neighborhoods, and schools. Exposure to interpersonal violence has a very serious impact on most youth. Focusing on violence prevention remains a vital component of providing comprehensive health care for all youth.

Premji SS, McNeil DA, Scotland J. Regional neonatal oral feeding protocol: changing the ethos of feeding preterm infants. *J Perinat Neonatal Nurs* 2004; 18(4):371-84. Abstract: The Calgary Health Region Neonatal Oral

Feeding Protocol is the culminating work of a broad range of healthcare professionals, including staff nurses, nurse practitioners, nurse educators, nurse managers, dietitians, lactation consultants, clinical nurse specialists, and occupational therapists. The protocol represents a synthesis of research evidence and expert opinion pertaining to the introduction and management of oral milk feedings for high-risk infants in the neonatal intensive care unit. This evidence-based neonatal oral feeding protocol is presented to share knowledge and skill required to create positive feeding experiences while assisting high-risk infants to achieve full oral feedings. Goals of this project include promoting consistent neonatal nursing feeding practices and changing the ethos in relation to feeding interactions between caregiver and infant in the neonatal intensive care unit. This culture change will assist nurses to identify what is unique about their professional practice, which is of particular importance given the skill mix resulting from hospital understaffing and a growing nursing workforce shortage.

Premji SS, Paes B, Jacobson K, Chessell L. Evidence-based feeding guidelines for very low-birth-weight infants. *Adv Neonatal Care* 2002; 2(1):5-18. Abstract: Clinical practice guidelines (CPG) for the nutritional management of premature infants are limited. This project focused on the development of a research-based enteral feeding CPG for infants of < 1,500 g. The CPG was based on an extensive literature review and developed through a process of consensus decision making by a team of clinical researchers. Infants that weigh < 1,000 g initiate minimal enteral nutrition (MEN) at 48 hours; nutritional feedings begin on day 5 to 6 of life. For infants between 1,000 and 1,500 g, nutritional feedings begin at 48 hours and are advanced at a rate of less than 30 mL/kg per day. The benefits and risks of continuous versus intermittent nasogastric tube feeding were inconclusive; therefore, the CPG does not stipulate a feeding method. Breast milk is used preferentially, and specific guidelines for the definition and management of feeding intolerance are provided. A follow-up study testing this CPG has been completed and is published in the original research section of this issue.

Price JH, Islam R, Gruhler J, Dove L, Knowles J, Stults G. Public perceptions of child abuse and neglect in a midwestern urban community. *J Community Health* 2001; 26(4):271-84. Abstract: This study found that the majority of urban

adults did not believe that any of the characteristics of children posed to them predisposed a child to abuse. In contrast, 40% of respondents claimed child abuse could not occur in a family like the one in which they grew up. The majority perceived only one characteristic, alcohol abuse, as a characteristic of child abusers. Few respondents (10%) believed that child abusers could not be helped, and 25% were not sure. Adults' perceptions of child abuse and abusers varied by sex, age, socioeconomic status, and whether the respondents had children. The data indicate that there are significant deficits in the respondents' knowledge of child abuse and neglect.

Price JM, Glad K. Hostile attributional tendencies in maltreated children. *J Abnorm Child Psychol* 2003; 31(3):329-43.

Abstract: The hostile attributional tendencies of maltreated children in elementary school across key relationship figures (i.e., parents, teachers, and peers), the relation between children's hostile attributional tendencies and the frequency and severity of maltreatment, and the role of children's hostile attributions of their parents in mediating the relation between maltreatment and children's hostile attributions of unfamiliar peers were examined. The sample consisted of 44 maltreated and 56 nonmaltreated children (females = 51) of mixed ethnicity. Subjects were administered a 20-item measure of attributional processes. The results indicated that relative to nonmaltreated children, physically abused boys were more likely to attribute hostile intentions to a variety of relationship figures, including their parents, an unfamiliar teacher, their best friend, and unfamiliar peers. A positive relation was also found between the frequency of physical abuse and hostile attributional tendencies among males. Finally, support was found for the role of children's hostile attributions of their mothers in mediating the relation between physical abuse and children's hostile attributions of unfamiliar peers. The results support a link between physical abuse and hostile attributional tendencies in children in early elementary school.

Prudent N, Johnson P, Carroll J, Culpepper L. Attention-deficit/hyperactivity disorder: presentation and management in the Haitian American child. *Prim Care Companion J Clin Psychiatry* 2005; 7(4):190-7. Abstract: A case study of a young Haitian American is presented that is illustrative of cultural issues that influence care of those with attention-deficit/hyperactivity disorder (ADHD). Medications are the preferred treatment for ADHD and can be combined with psychological intervention. However,

many Haitians and Haitian Americans see psychoactive medications as leading to substance abuse or mental illness. Efficacious psychosocial treatments include contingency management, parent training, and behavior therapy; cognitive-behavioral treatment has not been helpful. Complementary and alternative medicine might have appeal; primary care physicians can help families to assess such treatments and not to be enticed by expensive ones of little benefit. A determinant of the treatment a family pursues is their perception of the cause of the ADHD behaviors. While there is no term for ADHD in the Haitian-Creole language, in the Haitian culture the behaviors consistent with the diagnosis might be interpreted as indicating a poorly raised child whose behavior could be modified by parental discipline, an intentionally bad child, or a psychically victimized child suffering from an "unnatural" condition. "Natural" ailments are attributed to natural forces (e.g., wind, temperature), while "unnatural" ones are attributed to bad spirits or punishment by God. Families may "lift their feet" (Leve pye nou: to see a Hougan or voodoo priest) to determine the unnatural cause. Haitian Americans often combine therapeutic foods that are considered cold in nature, natural sedatives and purgatives from herbal medicine, religious treatments, and Western medicine. Immigrants often lack support of extended families in an environment not supportive of their interpretation of child behaviors and traditionally accepted parental disciplinary style. Stigma, language, cultural conceptions, concerns about governmental agencies, and physician bias can all be barriers to care for immigrant families. Primary care and behavioral integration are useful in managing families from other cultures.

Pugh LC, Milligan RA, Frick KD, Spatz D, Bronner Y. Breastfeeding duration, costs, and benefits of a support program for low-income breastfeeding women. *Birth* 2002; 29(2):95-100.  
 Abstract: BACKGROUND: Breastfeeding can ameliorate some of the complex health issues faced by low-income families. Women who breastfeed and their infants have lower health care costs compared with those who formula feed. Increasing the duration of breastfeeding is recognized as a national priority, particularly for low-income women. This community-based randomized clinical trial involving low-income mothers compared usual care with an intervention comprising hospital and home visits, and telephone support by a community health nurse/peer counselor team for 6 months after delivery. METHODS: Forty-one women were recruited after delivery of a full-term singleton infant and randomly assigned to intervention or usual care groups. RESULTS: Women receiving the community health intervention breastfed longer than the women receiving usual care. The infants in the intervention group had fewer sick visits and reported use of fewer medications than infants in the usual care group. The intervention cost (\$301/mother) was

partially offset by cost savings on formula and health care. CONCLUSIONS: Community health nurse and peer counselor support can increase breastfeeding duration in low-income women, and has the potential to reduce total costs including the cost of support.

Puklova V, Cerna M, Smid J *et al.* Copper saturation pathways of the urban population in the Czech Republic. *Cent Eur J Public Health* 2001; 9(3):119-25.  
 Abstract: The estimation of the copper saturation pathways of the Czech urban population is presented. The data on copper concentrations proceed from the System of monitoring the environmental impact on population health in the Czech Republic in the period 1994-1998. The copper concentrations were monitored in foodstuffs from the commercial network, in drinking water at the outlets of the waterworks and in the public water main networks, and in the ambient air. The copper levels were measured also in biological material to obtain the data on the copper saturation of the population under monitoring. The copper intake from foodstuffs and drinking water did not vary significantly either in the particular years of monitoring or individual cities. The same concerns also the copper levels in biological material. The total copper intake for an average adult was estimated to be 20.2 micrograms/kg b.w./d., i.e. 1300 micrograms/d. Over 99% of the total intake was that from the diet. The exposure from the intake of drinking water as well as from ambient air was low. The total daily intake lies in the interval 1000-2000 micrograms/d which is usually found in the similar studies of the copper intake. It represents only 40% of the daily dietary copper intake recommended by the JECFA FAO/WHO Commission, 1982. The copper levels in biological material did not differ from the reference values, and did not indicate any evincible hyposaturation of the population with copper.

Puligheddu M, de Munck JC, Stam CJ *et al.* Age distribution of MEG spontaneous theta activity in healthy subjects. *Brain Topogr* 2005; 17(3):165-75.  
 Abstract: This study investigates the possible relevance of distribution and age variation of spontaneous theta activity (4-8 Hz) in normal subjects using magnetoencephalography (MEG) recordings. Spontaneous theta was recorded with a 151-channel MEG in healthy subjects; moreover, in a group of 10 subjects, simultaneous MEG-EEG was recorded in order to compare the two methods. Theta was divided in two sub-bands: T(A) (4-6 Hz) and T(B) (6-8 Hz). The pre-processed data were transformed into the frequency domain by Fast Fourier Transform (FFT)-based software by subdividing the data in epochs of 5 sec, on which FFT amplitudes are computed. Moreover, on all trials a simple model of a single

electric current embedded in a spherically symmetric conductor was fitted automatically to the magnetic fields and projected onto an averaged MRI. The results obtained show that FFT-based theta power spectrum was distributed in adults with the highest power over the posterior parietal and occipital areas with T(B) dominance. The dipole analysis resulted in a mid-sagittal distribution, though the youngest group displayed theta dipoles fitting more posteriorly respect to the adults and the elderly. These results suggest that spontaneous theta activity is a diffuse and pervasive rhythm which shows some different topographical distribution among the age groups. Whether the prevalent posterior distribution of theta is the expression of distinct networks or the outcome of complex dynamics are questions of possible relevance in the organization of higher order processes.

Pulkki L, Keltikangas-Jarvinen L, Ravaja N, Viikari J. Child-rearing attitudes and cardiovascular risk among children: moderating influence of parental socioeconomic status. *Prev Med* 2003; 36(1):55-63. Abstract: BACKGROUND: We examined associations of parental socioeconomic status (SES) and hostile maternal child-rearing attitudes with the insulin resistance syndrome (IRS) precursors in children. METHODS: The participants were 210 randomly selected healthy boys and girls who participated in the epidemiological Cardiovascular Risk in Young Finns study and who were 3, 6, and 9 years of age at the three study phases. Hostile maternal child-rearing attitudes were self-rated by the mothers. SES consisted of the years of education of the parents and family income. The IRS comprised serum insulin, high-density lipoprotein cholesterol, triglycerides, systolic blood pressure, and body mass index. RESULTS: Among boys, low parental SES and strict maternal discipline were associated with heightened somatic risk. Among girls, parental SES moderated the association between maternal child-rearing attitudes and somatic risk so that belonging to a high-SES family seemed to protect the girls against the adverse health effects of hostile mothering. CONCLUSIONS: The findings indicate that the psychosocial environment is differentially related to girls' and boys' somatic risk. It is concluded that belonging to high social class may buffer against childhood stress, while belonging to low social class may enhance vulnerability to stressors in childhood.

Punt J, Bonshek RE, Jaspan T, McConachie NS, Punt N, Ratcliffe JM. The 'unified hypothesis' of Geddes et al. is not supported by the data. *Pediatr Rehabil* 2004; 7(3):173-84.

Abstract: Inflicted head injury to the developing brain frequently results in serious disability. The pathogenesis of the neuraxial and ocular findings in infants believed to have suffered inflicted head injury remains the subject of considerable debate. Recent neuropathology studies of fatal cases of inflicted head injury and of a foetal/perinatal non-traumatic model

have led to the proposal that there is a 'unified hypothesis', the essential feature of which is hypoxic brain swelling secondary to cervicomedullary injury. It has been suggested that less than violent forces may be involved and even that some cases may not be due to trauma at all. The purpose of this paper is to provide a critical review of the data upon which these suppositions are based on a background of what is already known. It is submitted that there are serious flaws in the methodology; the conclusions reached cannot logically be drawn from the data; and the 'unified hypothesis' is not supported by the evidence. On the basis of the data presented, it is also difficult to sustain the secondary hypothesis purporting to describe a minority cohort with 'infantile encephalopathy with subdural and retinal bleeding' of non-traumatic causation.

Purcell R, Pathe M, Mullen PE. The prevalence and nature of stalking in the Australian community. *Aust N Z J Psychiatry* 2002; 36(1):114-20. Abstract: OBJECTIVE: This study examines the extent and nature of stalking victimisation in a random community sample. METHOD: A postal survey was distributed to 3700 adult men and women selected from the electoral roll in the State of Victoria. Outcome measures included the lifetime and annual cumulative incidence of stalking, the duration and methods of harassment, rates of associated violence and responses to victimisation. RESULTS: Almost one in four respondents (23.4%;432) had been stalked, the unwanted behaviour they were subjected to being both repeated and fear-provoking. One in 10 (197) had experienced a protracted course of stalking involving multiple intrusions spanning a period of at least one month. Women were twice as likely as men to report having been stalked at some time in their lives, though the rates of victimisation in the 12 months prior to the study did not differ significantly according to gender. Younger people were significantly more likely than older respondents to report having been stalked. Victims were pursued by strangers in 42% of cases. The most common methods of harassment involved unwanted telephone calls, intrusive approaches and following. Associated threats (29%) and physical assaults (18%) frequently arose out of the stalking. Significant social and economic disruption was created by the stalking for 63% of victims. Most sought assistance to manage their predicament (69%). CONCLUSIONS: The experience of being stalked is common and appears to be increasing. Ten percent of people have been subjected at some time to an episode of protracted harassment. Assaults by stalkers are disturbingly frequent. Most victims report significant disruption to their daily functioning irrespective of exposure to associated violence.

Purugganan OH, Stein RE, Silver EJ, Benenson BS. Exposure to violence and psychosocial adjustment among urban school-aged children. *J Dev Behav Pediatr* 2003; 24(6):424-30. Abstract: This study determines the relationship between psychosocial adjustment in school-aged children and one aspect of exposure to violence, the proximity of exposure, in terms of (1) "physical" proximity and (2) "emotional" proximity to the victims of violence. A convenience sample of 175 children aged 9 to 12 years from a primary care clinic of a large urban hospital were interviewed about their exposure to violence using the Children's Report of Exposure to Violence. Psychosocial adjustment was measured through maternal reports using the Child Behavior Checklist (CBCL) and the Personal Adjustment and Role Skills Scale (PARS III). Children were categorized into three groups according to their closest proximity to exposure to violence ("victim" > "witness" > exposure through other people's "report") and two groups according to emotional proximity (victim was a "familiar person" or "stranger"). All children (23/175) who scored above the CBCL clinical cutoff (T score > 63) were witnesses or victims of violence. The CBCL total T scores (higher score = more maladjustment) showed that the "victims" group (mean 52.4) scored significantly higher than the "witness" group (mean 50.0) and "report" group (mean 47.4). The PARS III total scores (lower scores = more maladjustment) showed that the "victims" group (mean 87.5) scored significantly lower than the "witness" group (mean 93.1) and "report" group (mean 98.2). The relationship of the child to the victim was not associated with significantly different CBCL and PARS III scores. Children exposed to more proximal forms of violence as victims or witnesses exhibited more psychosocial maladjustment.

Qari FA. Precipitating factors for diabetic ketoacidosis. *Saudi Med J* 2002; 23(2):173-6. Abstract: OBJECTIVE: The aim of this study is to identify the precipitating factors from a medical and social point of view, in addition to discussing some clinical and laboratory aspects of diabetic ketoacidosis. METHODS: Sixty-eight patients were admitted to King Abdulaziz University Hospital, Jeddah, Kingdom of Saudi Arabia, over a 2 year period, (April 1999 through to April 2001). Diagnosis of diabetic ketoacidosis was based on: clinical features, serum sugar >12 mmol/L with ketonuria, bicarbonate and base deficit. RESULTS: The mean age was 22.5 years (0.5-87) years with a male to female ratio of 1.4:1. Poor compliance to continue the treatment and infection were the most common precipitating factors being responsible for 54.4% and 28% cases. A low mortality rate of 2.9% in our study compared favorably with other studies, which contributed to a high level of

medical care in King Abdulaziz University Hospital. CONCLUSION: Diabetic ketoacidosis is a fatal complication among our diabetic patients. Implementing a patient education program to increase awareness of the disease is the most important step in the prevention of this complication. The authorities should ensure availability of insulin to all patients, either free or at lower prices. The role of cultured and socioeconomic factors in aggravating or precipitating diabetic ketoacidosis should always be considered and where possible, eliminated

Qouta S, Punamaki RL, El Sarraj E. Prevalence and determinants of PTSD among Palestinian children exposed to military violence. *Eur Child Adolesc Psychiatry* 2003; 12(6):265-72. Abstract: The prevalence and determinants of PTSD were assessed among 121 Palestinian children (6-16 years; 45% girls and 55% boys) living in the area of bombardment. The mothers (21-55 years) and the children themselves reported their exposure to military violence (being personally the target of violence or witnessing it towards others) and symptoms of posttraumatic stress disorders (PTSD: intrusion, avoidance and hypervigilance). The results showed that 54% of the children suffered from severe, 33.5 % from moderate and 11 % from mild and doubtful levels of PTSD. Girls were more vulnerable; 58% of them suffered from severe PTSD, and none scored on the mild or doubtful levels of PTSD. The child's gender and age, mother's education and PTSD symptoms were significant, and the exposure to traumatic experiences marginally significant determinants of children's PTSD symptoms. The most vulnerable to intrusion symptoms were younger girls whose mothers showed a high level of PTSD symptoms, whereas those most vulnerable to avoidance symptoms were children who had personally been targets of military violence and whose mothers were better educated and showed a high level of PTSD symptoms. The results are discussed in the context of military violence interfering with the protective function of family and home.

Quayle E, Taylor M. Child seduction and self-representation on the Internet. *Cyberpsychol Behav* 2001; 4(5):597-608.

Abstract: This paper presents a case study of a man charged with the offense of downloading child pornography from the Internet. He had used the Internet to traffic child pornography, and, in addition, to locate children to abuse, to engage in inappropriate sexual communication with children, and to communicate with other pedophiles. Such offenses were facilitated by self-representing in Chat rooms as both a child and an adult. The case study illustrates how such offenders move through a repertoire of

offending behavior and discusses the role that the Internet can play in supporting inappropriate and disinhibited sexual behavior that victimizes children through the trading of child pornography and possible child seduction. The Internet is seen to play a unique role in allowing individuals to self-represent aspects that might otherwise remain hidden or dormant.

Quayle E, Taylor M. Model of problematic internet use in people with a sexual interest in children. *Cyberpsychol Behav* 2003; 6(1):93-106.

Abstract: Agencies working with sex offenders are starting to see the emergence of people with a sexual interest in children who meet some of their needs through the use of child pornography, or the seduction of children, through the Internet. While CBT models dominate our understanding of sex offenders, there has been little research into the role that such new technologies may play in offending behavior. Data from the COPINE project has been used to generate a model of such offending behavior that emphasizes the role of cognitions in both the etiology, engagement with and problematic use of the Internet for those with a sexual interest in children. Such a model seeks to incorporate contemporary thinking about the role of cognitions in Pathological Internet Use, but applies this from a nonpathological perspective. This model is a first step towards providing a conceptual framework for such offending that will help inform both assessment and therapy.

Quillin JM, Jackson-Cook C, Bodurtha J. The link between providers and patients: how laboratories can ensure quality results with genetic testing. *Clin Leadersh Manag Rev* 2003; 17(6):351-7.

Notes: GENERAL NOTE: KIE: 41 refs.. GENERAL NOTE: KIE: KIE Bib: genetic screening Abstract: Advances in genetic testing technology can provide important opportunities for health improvement. Simultaneously, they entail complexity in laboratory analysis and interpretation. The nature of genetic testing may engender implications distinct from other diagnostic tests. In this article, we summarize these implications, including the role of informed consent; quality assurance in diagnostic testing services; interpretation of the test results; patient support; appropriate disclosure; and regulations relevant for laboratories involved with genetic tests. Research and clinical laboratories need to stay abreast of these advancing technologies and their implications for health-care patients and providers. Collaboration between testing personnel, geneticists, and other health-care providers is necessary to ensure that patients receive the full benefits from testing, including a clear understanding of their genetic test information.

Quin G, Evans R. Accident and emergency department access to the child protection register: a questionnaire survey. *Emerg Med J* 2002; 19(2):136-7.

Abstract: OBJECTIVES: To ascertain how UK accident and emergency (A&E) departments access the child protection register, their levels of satisfaction with that access and their criteria for checking the register. METHODS: A postal questionnaire was sent to 254 "major" A&E departments listed in the 1996 British Association for Accident and Emergency Medicine directory. RESULTS: 190 questionnaires were returned (response rate 75%). Ninety (48%) responding departments access the register through the duty social worker, 33 (17%) use a computerised copy, 32 (17%) a hard copy and 27 (14%) a combination. Twenty seven of 33 respondents (82%) using a computerised copy were satisfied with their mode of access. This compares with figures of 21 (66%) for hard copy, 45 (50%) for duty social worker and 14 (50%) for a combination. No departments using the duty social worker checked all patients routinely compared with 23 (72%) for hard copy, 22 (67%) for computer copy and 12 (44%) for departments using a combination of modes of access. CONCLUSION: There is no uniformity of the way in which UK A&E departments access the child protection register and there is also substantial variation in the criteria used to check the register. This survey suggests that the most common form of access (via the duty social worker) often fails to meet the needs of A&E departments, principally because it takes so long.

Quinlivan JA, Evans SF. A prospective cohort study of the impact of domestic violence on young teenage pregnancy outcomes. *J Pediatr Adolesc Gynecol* 2001; 14(1):17-23.

Abstract: INTRODUCTION: The incidence of domestic violence among pregnant Australian teenagers is higher than rates reported for the general community. However, there are limited data that address the impact of this abuse upon pregnancy outcome. We have examined the significant antenatal associations of domestic violence in young teenage pregnancy, and the impact of this abuse upon pregnancy outcome. DESIGN, SETTING, PARTICIPANTS: A multicenter prospective cohort study was performed between January 1, 1997 and June 30, 1999. Patients were interviewed and completed questionnaires in the antenatal period to establish whether they were victims of domestic violence. Labor and delivery details were independently collated after discharge for mother and infant. Data were analyzed using an analysis of variance, with a P-value of 0.05 considered significant. RESULTS: Of 537 patients enrolled in the study, 157 (29.2%) were victims of domestic violence; 380 (70.8%) were not and acted as pregnant teenage controls. Key findings were that teenage victims of domestic violence (VDV) were more likely to smoke, drink alcohol, or use illegal drugs than controls ( $P < 0.0001$ ). VDV had a higher incidence of infectious morbidity and Pap smear abnormalities ( $P < 0.007$ ) and psychosocial pathology ( $P < 0.0001$ ) than controls. A

- higher incidence of puerperal and neonatal morbidity was observed in VDV and their newborns compared to controls ( $P < 0.007$ ). The estimated cost of hospital care for teenage VDV was double that of the Australian average. CONCLUSION: We need to identify all teenage mothers exposed to domestic violence and provide them with expert intervention services. Early intervention programs are likely to be cost effective.
- Quinn J. The Children's Aid Society community schools: a full-service partnership model. *New Dir Youth Dev* 2005; (107):15-26, table of contents. Abstract: In 1989, the Children's Aid Society (CAS) created an unprecedented partnership with the New York City Board of Education by developing a comprehensive response to the pressing needs of children and families in the northern Manhattan neighborhood of Washington Heights. After three years of careful planning, CAS and the New York City public schools opened the first community school at Intermediate School 218, offering a full array of supports, services, and learning opportunities. Adding, on average, one partnership school per year and remaining very flexible in adapting its model to the individual needs of each community, CAS now has thirteen community schools around New York City. The model's flexibility is seen also in the success of its national and international adaptation-an intentional part of CAS's work.
- Quinn TL. Sexual orientation and gender identity: an administrative approach to diversity. *Child Welfare* 2002; 81(6):913-28. Abstract: Research indicates that gay, lesbian, bisexual, transgender, and questioning (GLBTQ) teens in the care of a northeastern child welfare department do not receive adequate services due to the workers' homophobic attitudes. These teens are at high risk for alcohol and drug abuse, homelessness, prostitution, and suicide. A training module was developed for administrators. Pretest and posttest instruments measured their education and support of GLBTQ issues before and after the training.
- Quintana Y, Nambayan A, Ribeiro R, Bowers L, Shuler A, O'Brien R. Cure4Kids - building online learning and collaboration networks. *AMIA Annu Symp Proc* 2003; 978. Abstract: The International Outreach Program of St. Jude Children's Research Hospital has been developing programs to help countries with limited resources develop treatment centers to treat children with catastrophic diseases such as pediatric cancer and AIDS. Cure4Kids ([www.cure4kids.org](http://www.cure4kids.org)) is the Internet learning network that delivers medical education to doctors and nurses on pediatric cancer and AIDS. The objective of Cure4Kids is not only education, but also to provide tools for communications and collaborations among individuals.
- Rabahi MF, Rodrigues AB, Queiroz de Mello F, de Almeida Netto JC, Kritski AL. Noncompliance with tuberculosis treatment by patients at a tuberculosis and AIDS reference hospital in midwestern Brazil. *Braz J Infect Dis* 2002; 6(2):63-73. Abstract: INTRODUCTION: In developing countries, there is little information about the risk factors that predict noncompliance with tuberculosis (TB) treatment in hospitals. OBJECTIVE: This study analyzes possible factors associated with noncompliance with TB treatment among patients treated at HAA. DESIGN: A retrospective cohort study was made including all patients who initiated TB treatment at HAA, from January to December 1998. A standard form was used to review medical records and to collect data on each patient. This data was evaluated in comparison with data from the state TB control program. RESULTS: Of the 341 patients included in the study, 186 (61.2%) were considered cured and 67 (22%) were non-compliant. The factors associated with noncompliance were: previous anti-TB treatment (RR = 1.95, 95% CI 1.29 to 2.93), prescription of drugs other than the standard first-line regimen proposed by the Brazilian Health Ministry (Rifampin + Isoniazide + Pyrazinamide) (RR = 0.54, 95% CI 0.35 to 0.83), the need for hospitalization (RR = 2.19, 95% CI 1.46 to 3.29) and non-inclusion in the hospital's TB Control Program for treatment follow up (RR = 0.54, 95% CI 0.35 to 0.82). SETTING: Anuar Auad Hospital (HAA) Goiania, Goias, Brazil. CONCLUSION: Our results indicate the importance of establishing Tuberculosis Control Programs in hospitals, while paying special attention to patients with risk factors for noncompliance with TB treatment.
- Raboteg-Saric Z, Rijavec M, Brajsa-Zganec A. The relation of parental practices and self-conceptions to young adolescent problem behaviors and substance use. *Nord J Psychiatry* 2001; 55(3):203-9. Abstract: The object of the present research was to examine the role of parenting practices for young adolescent psychosocial adjustment and self-regulation problems. The sample included 287 sixth- and seventh-grade subjects from intact families. The participants completed a questionnaire that measured variables including family interaction, parental involvement in children's activities, parental support, joint decision-making, and monitoring of children's behavior. Children's involvement with friends, after-school activities, school achievement, and self-reported externalizing behaviors (problem behaviors, cigarette and alcohol use) were also measured. Self-concept domains (scholastic competence, social acceptance, and behavioral conduct) were assessed with Harter's Self-Perception Profile. The findings indicated that self-conceptions of positive behavioral conduct and higher parental monitoring of children's activities were consistently negatively related to young girls' and boys' behavior problems and substance use. Parental monitoring was higher for girls and for younger

children. Lower monitoring was also related to children's pattern of after-school activities that were connected to at-risk behavior. Parental involvement and supervision of children's day-to-day activities seem particularly important in socializing children's behavior at the time of early adolescence.

Radimer KL, Radimer KL. Measurement of household food security in the USA and other industrialised countries. *Public Health Nutr* 2002; 5(6A):859-64. Abstract: OBJECTIVE: To describe the history and current status of household food security measurement. CONCLUSIONS: In the 1980s evidence of rising levels of hunger was a concern for many, but disputed by some, Americans. Acknowledgement and quantification of hunger was hindered by the lack of an accepted definition and measure of hunger. Qualitative research at Cornell provided a conceptual framework, description, definition and survey items for hunger. The Community Childhood Hunger Identification Project developed an instrument used in numerous communities. Based upon these initiatives, widely accepted definitions of hunger and food insecurity, and the US Household Food Security Module for its measurement, now exist. The module classifies households as food-secure, or food-insecure without hunger or with moderate or severe hunger, and contains household-, adult- and child-referent items. Its inclusion in the Current Population Survey (CPS) since 1995 has yielded annual estimates of food insecurity. A six-item short form of the module, for surveys with severe time constraints, classifies households only as food-secure or food-insecure without or with hunger and contains no child-specific items. Surveys using the 18-item or short-form module can compare results with published national data from the CPS. Information about the module is available at <http://www.ers.usda.gov/briefing/foodsecurity> and <http://www.fns.usda/fsec>. Current research on food security measurement includes measurement of individual food insecurity and hunger, module performance regarding hunger duration and frequency, performance of the module in population sub-groups, and the effect of translations on module meaning and performance. National surveys in Canada, New Zealand and Australia also have measured food security.

Radonovich KJ, Mostofsky SH. Duration judgments in children with ADHD suggest deficient utilization of temporal information rather than general impairment in timing. *Child Neuropsychol* 2004; 10(3):162-72. Abstract: Clinicians, parents, and teachers alike have noted that individuals with ADHD often have difficulties with "time management," which has led some to suggest a primary deficit in time perception in ADHD. Previous studies have implicated the basal ganglia, cerebellum, and frontal lobes in time estimation and production, with each region purported to make different contributions to the processing and

utilization of temporal information. Given the observed involvement of the frontal-subcortical networks in ADHD, we examined judgment of durations in children with ADHD (N = 27) and age- and gender-matched control subjects (N = 15). Two judgment tasks were administered: short duration (550 ms) and long duration (4 s). The two groups did not differ significantly in their judgments of short interval durations; however, subjects with ADHD performed more poorly when making judgments involving long intervals. The groups also did not differ on a judgment-of-pitch task, ruling out a generalized deficit in auditory discrimination. Selective impairment in making judgments involving long intervals is consistent with performance by patients with frontal lobe lesions and suggests that there is a deficiency in the utilization of temporal information in ADHD (possibly secondary to deficits in working memory and/or strategy utilization), rather than a problem involving a central timing mechanism.

Raghavan C, Swan SC, Snow DL, Mazure CM. The mediational role of relationship efficacy and resource utilization in the link between physical and psychological abuse and relationship termination. *Violence Against Women* 2005; 11(1):65-88. Abstract: This study examines the roles of physical and emotional abuse and resource utilization, relationship efficacy, and childhood abuse on relationship status (together or separated) in a sample of 69 low-income, nonsheltered battered women. Separate path models were conducted for physical and psychological abuse. Increased physical abuse was related to separated status, increased resource utilization, and decreased efficacy. The effect of physical abuse on status was mediated by resource utilization and efficacy, whereas the effect of psychological abuse on status was partially mediated only by utilization. Increased childhood abuse was associated with together status. Baseline psychological but not physical abuse predicted a longer term separated status thereby suggesting that the effects of psychological abuse may be enduring.

Rahi JS, Manaras I, Tuomainen H, Hundt GL. Meeting the needs of parents around the time of diagnosis of disability among their children: evaluation of a novel program for information, support, and liaison by key workers. *Pediatrics* 2004; 114(4):e477-82. Abstract: OBJECTIVE: Key worker programs for families of children with disabilities, to promote information provision, emotional support, and liaisons among different agencies, have long been advocated but not extensively implemented. We report the impact on the experiences of parents and the practices of health care professionals of a novel, hospital-based, key worker service (Community Link Team [CLT]), implemented in the pediatric ophthalmology department of Great Ormond Street Hospital (London, United Kingdom). DESIGN, SETTING, AND

**PARTICIPANTS:** The CLT included 2 members, 1 of whom was present during the first outpatient assessment by the consultant ophthalmologist of any child newly diagnosed as visually impaired (corrected acuity of 6/18 or worse in the better eye) and accompanied the family during other assessments performed during that visit. A dedicated room was used by the CLT members to spend time with each family after completion of the clinical assessments. The CLT members reiterated and/or clarified clinical information already provided, specifically advised the families about visual stimulation programs and the benefits and purpose of visual impairment certification, and provided information about educational and social services. The same CLT member met the family at subsequent visits to the department and acted as the first point of contact for parents. Parents of children newly diagnosed with visual impairment and/or ophthalmic disorders at Great Ormond Street Hospital participated in a 2-stage study to assess their needs, their views about the processes of care, and their overall satisfaction. The study included a questionnaire survey with 2 standard instruments, ie, the Measure of Processes of Care, specifically developed and used to assess parents' views of the degree to which health services for a range of childhood disorders are family-centered, and the short form of the Client Satisfaction Questionnaire, used to assess overall parental satisfaction or dissatisfaction with services in the preceding year, as in other studies of parental satisfaction with pediatric services. This was followed by in-depth individual interviews with a subsample of parents who returned completed questionnaires. The views of families with experience with the new service (CLT) were compared with those without. The experiences of health care professionals before and after implementation of the service were elicited through group interviews and were compared. We recognized that any differences would be attributable to both the direct effects of the CLT, ie, actual services provided by the team, and indirect effects, ie, broader changes in approaches or practices within the department resulting from shifting roles and responsibilities regarding specific elements of management. Therefore, both the specific tasks/activities undertaken by the CLT and broader changes in practices within the department were identified. **RESULTS:** Seventy-nine families from the pre-CLT group and 68 from the post-CLT group (68% and 65% of those invited, respectively) participated in the questionnaire survey, of which 29 and 19 (71% and 79% of those invited), respectively, took part in interviews. The 2 groups were comparable with respect to sociodemographic and clinical characteristics. Parents and health care professionals agreed that the CLT provided important information and facilitated access to specific services, while providing both emotional and social support and facilitating meetings with other families with children with similar conditions. A number of key generic components of the

service were identified. First, provision, within the outpatient setting, of a dedicated "quiet room" and office space for key workers was an essential physical requirement. Second, early identification of the key workers as the parents' point of contact was essential; this was achieved in this case by the CLT members attending the first consultation, combined with their detailed debriefing of families at the end of the outpatient visit. Third, the adoption of certain tasks by the key workers, including some previously undertaken by ophthalmologists, helped to define the liaison role of the program. These tasks included discussing the process and benefits of visual impairment certification, contacting the advisory teacher for the visually impaired, and providing written reports to educational and social services; analogous tasks would exist for other disabilities. **CONCLUSIONS:** Research on the needs of families of visually impaired children has been limited but indicates that, as with other childhood disabilities, the greatest needs during the critical period around diagnosis are for information, especially about educational and social services, and emotional support from professionals, informal and formal social networks, and support groups. Although not widely implemented or studied, key worker programs for families of visually impaired children, particularly in the context of multidisciplinary visual impairment teams, have been advocated, on the basis of their potential to facilitate coordination of health, educational, and social services. The model of such provision evaluated in this study reflects the fact that it was established as an outpatient service in a tertiary referral center for pediatric ophthalmology in the United Kingdom, with the specific structure and specialized roles for health care professionals that this requires. Different models might be more suitable in other settings in the United Kingdom or elsewhere. However, the important general lessons learned should guide implementation of such services for families of children with other disabilities. The recently launched National Service Framework for Children provides a new context and standards for meeting the needs of disabled children and their families in the United Kingdom and may also guide initiatives elsewhere. The findings of this study support implementation of programs for information provision, support, and liaison by key workers in all specialized centers for the assessment and diagnosis of children with serious visual problems. Implementation of similar services for families with children with other disabilities is likely to be equally valuable.

Raine A. Biosocial studies of antisocial and violent behavior in children and adults: a review. *J Abnorm Child Psychol* 2002; 30(4):311-26. Abstract: Despite increasing knowledge of social and biological risk factors for antisocial and violent behavior, we know surprisingly little about how these two sets of risk factors interact. This paper documents 39 empirical examples of biosocial interaction effects

for antisocial behavior from the areas of genetics, psychophysiology, obstetrics, brain imaging, neuropsychology, neurology, hormones, neurotransmitters, and environmental toxins. Two main themes emerge. First, when biological and social factors are grouping variables and when antisocial behavior is the outcome, then the presence of both risk factors exponentially increases the rates of antisocial and violent behavior. Second, when social and antisocial variables are grouping variables and biological functioning is the outcome, then the social variable invariably moderates the antisocial-biology relationship such that these relationships are strongest in those from benign home backgrounds. It is argued that further biosocial research is critical for establishing a new generation of more successful intervention and prevention research.

Rajab LD. Traumatic dental injuries in children presenting for treatment at the Department of Pediatric Dentistry, Faculty of Dentistry, University of Jordan, 1997-2000. *Dent Traumatol* 2003; 19(1):6-11. Abstract: Data pertaining to traumatic dental injuries of children seeking care at the teaching clinics of the Department of Pediatric Dentistry, Faculty of Dentistry, University of Jordan over a period of 4 years were analyzed. The prevalence of traumatic dental injuries was 14.2% from 2751 subjects. The peak incidence of injury was 10-12-year age group. Boys were more affected (18.3%) than girls (10.1%). Most injuries occurred at home (63.2%), and falls were the leading cause of injuries (49.9%). Most injuries involved one tooth (69.3%) and maxillary central incisors were the most affected teeth (90.4%). The commonest injury was uncomplicated crown fracture (62.5%), then complicated crown fracture (28.7%). Only 17.1% of children sought treatment the same day or the day after the injury. At the initial examination, cases seen after a long post-traumatic period required more complicated treatment than those presented within a short time period. Preventive educational program should be instituted in Jordan, directed at parents and school teachers to inform them about the importance of traumatic dental injuries and the benefit of immediate attendance for dental treatment. Furthermore, improving the knowledge of dental practitioners through continuing education would also help in minimizing sequelae of traumatic dental injuries.

Rakow T. Differences in belief about likely outcomes account for differences in doctors' treatment preferences: but what accounts for the differences in belief? *Qual Health Care* 2001; 10 Suppl 1:i44-9. Abstract: Doctors, patients, and their relatives face a

complex decision when there are multiple treatment options that differ in their profiles of risk and benefit over time. Doctors from a single specialist paediatric cardiac unit participated in a correlational study that used a novel tool (subjective multi-state survival graphs) to elicit their beliefs about the likely outcome of different treatments. Doctors' preferences were more closely related to their beliefs about long term, rather than short term, outcomes. This is consistent with placing greater value on far future than on immediate life years, highlighting the importance of incorporating patients' values for these outcomes into decisions of this kind. Beliefs about likely outcomes differed with whether or not doctors encountered former paediatric patients who were now adults, illustrating the difficulty of deciding what risk information should be available when the evidence base on outcomes is limited. Some problems of risk communication are identified, and the value of multi-state survival graphs as an aid to communication is discussed.

Rakowski E. Who should pay for bad genes? *Calif Law Rev* 2002; 90(5):1345-414. Notes: GENERAL NOTE: KIE: 110 refs. GENERAL NOTE: KIE: KIE Bib: health care/economics; genetic intervention; wrongful life Abstract: Parents have long been able to influence the genetic composition of their children through their choice of a reproductive partner, if only very approximately. They are, however, increasingly able to determine the genetic make-up of their children in other, more precise ways, such as by selecting a particular gamete or embryo or by genetically modifying an embryo prior to artificial implantation. This Article discusses parents' obligations to their children and other members of the community stemming from their children's genes. In a just state, it argues, parents would be responsible for redressing any genetic disadvantage their children suffer as a result of parents' voluntary actions. Within the context of a liberal egalitarian account of distributive justice, this responsibility might most fairly be discharged through a compulsory insurance plan that provides compensation to genetically disadvantaged children when they might have had non-disadvantaged children instead would in some circumstances incur greater liability, because they could not fairly push the cost of their choices off on other members of the insurance pool. The Article also asks whether parents wrong a child by allowing it to be born with a genetic impairment when, had they taken steps to remove the impairment, the unimpaired child they had would have been a different person from the genetically disadvantaged child because the better-off child's capacities and experiences differed considerably from those that the disadvantaged child would have had. Contrary to many people's moral intuitions, the Article argues that parents do not wrong such a child. Nevertheless, parents remain morally obligated to bear any added costs occasioned by the child's impairment.

- Any other approach would allow them unjustly to shift the burden of their choices to other parents. Finally, the Article takes up the much debated question of whether parents harm a child by allowing it to be born with a life not worth living when they could have prevented its birth. It suggests that the answer to this question should be irrelevant to parents' legal liability. Acting on behalf of the parental insurance pool, the state may nonetheless adopt a variety of measures to help potential parents avoid giving birth to such children, which one can assume virtually all would prefer.

- Ramaswamy S, Madaan V, Qadri F *et al.* A primary care perspective of posttraumatic stress disorder for the Department of Veterans Affairs. *Prim Care Companion J Clin Psychiatry* 2005; 7(4):180-7; quiz 188-9. Abstract: Posttraumatic stress disorder (PTSD) is a major mental disorder associated with significant morbidity, psychosocial impairment, and disability. The diagnosis of PTSD can be missed in a primary care setting, as patients frequently present with somatic complaints or depression and are often reluctant to discuss their traumatic experiences. As recent studies of veterans returning from the Gulf War and the Iraqi War suggest high rates of PTSD, the U.S. Department of Veterans Affairs (VA) Hospitals are gearing up to face this challenge. It is important to screen these veterans for symptoms of PTSD and make an appropriate referral if required. In this article, we attempt to review PTSD with a special focus on the VA population. In addition to discussing the epidemiology, diagnosis, and treatment options for PTSD, we also suggest screening questions for both combat-related and military sexual trauma-related PTSD.
- Randall B, Wilson A. The 2000 Annual Report of the Regional Infant and Child Mortality Review Committee. *S D J Med* 2001; 54(11):447-8. Abstract: The 2000 Annual Report of the Regional Infant and Child Mortality Review Committee (RICMRC) is presented. Our Regional (Minnehaha, Lincoln, Turner, and McCook Counties) incidence for Sudden Infant Death (SIDS) was much lower in 2000 than seen previously in 1999 and 1998. It remains to be seen if this is a true reduction in the incidence of SIDS in our Region or simply a random fluctuation in the SIDS rate amplified by the relatively small number of Regional infant deaths. We are hopeful that the emphasis on the Back-to-Sleep program has been in part contributory towards the reduction in the number of SIDS. Accidental infant deaths in our report however emphasizes that Back-to-Sleep implies not only supine sleeping but also sleeping in a safe sleeping environment, including the avoidance of soft bedding. RICMRC serves not only as a data collection committee, but also actively engages in community education programs directed towards providing a safer environment for our children.
- Randall B, Wilson A. The 2001 annual report of the Regional Infant and Child Mortality Review Committee. *S D J Med* 2002; 55(11):471-5. Notes: CORPORATE NAME: Regional Infant and Child Mortality Review Committee Abstract: The annual report of the Regional Infant and Child Mortality Review Committee (RICMRC) is attached. This Committee has as its mission the review of infant and child death so that information can be transformed into action to protect young lives. The Committee review area in 2001 included South Dakota's Minnehaha, Turner, Lincoln, Moody, Lake, and McCook counties. In 2001 there were no deaths in this region due to Sudden Infant Death Syndrome (SIDS), however, there was one death due to positional asphyxia that represents the hazards of soft bedding and prone sleeping. In addition to this case, there were seven other deaths due to injury mostly representing immaturity in driving various vehicles. These data reflect the need to remain vigilant in the public campaign to promote "back to sleep" and safe sleeping environments for infant. The RICMRC invites other communities to join in its efforts to review deaths to prevent potential life-threatening hazards to children in their local environs.
- Randall B, Wilson A. The 2002 annual report of the Regional Infant and Child Mortality Review Committee. *S D J Med* 2003; 56(12):505-9. Abstract: The annual report of the Regional Infant and Child Mortality Review Committee (RICMRC) is attached. This Committee has as its mission the review of infant and child death so that information can be transformed into action to protect young lives. The 2002 review area includes South Dakota's Minnehaha, Turner, Lincoln, Moody, Lake, McCook, and Union counties. In 2002 there was one death in this region due to SIDS, plus one infant death due to positional asphyxia that illustrates the hazards of soft bedding and prone sleeping. These data reflect the need to remain vigilant in the public campaign to promote "back to sleep" and safe sleeping environments for infants. There were four other deaths due to accidental injury, mostly representing immaturity in driving various vehicles. In 2002 there were two child abuse homicides, and three teenage suicides. The RICMRC invites other communities to join in its efforts to review deaths to prevent potential life-threatening hazards to children in their local environs.
- Rao MR, Levine RJ, Wasif NK, Clemens JD. Reliability of maternal recall and reporting of child births and deaths in rural Egypt. *Paediatr Perinat Epidemiol* 2003; 17(2):125-31. Abstract: Demographic indicators such as fertility rates and infant mortality rates are often measured in census

surveys by interviewing mothers to obtain their pregnancy histories and child deaths. The validity of such surveys depends upon accurate recall of histories, truthful reporting of events and understanding of the questions posed. To measure the reliability of maternal reporting, two census surveys conducted in a rural Egyptian population were compared. Women between 15 and 55 years of age residing in 20 villages were asked their histories of live births, stillbirths and child deaths. An identical set of questions was posed 2 years later. Twice-monthly home visits were conducted in the intervening 2-year interval to identify accurately any new births, stillbirths and deaths occurring in the population. The maternal reports from the first census were combined with the prospectively identified births, stillbirths and deaths and compared with the maternal reports from the second census. For 1502 women, the discrepancies in the total number of births, stillbirths and child deaths reported between the two surveys were 0.6%, 4% and 0.6% respectively. However, when the consistency of responses was analysed, the proportion of women with discordant responses was 10%, 6% and 7% for the same measures. These results suggest that, despite the large number of births and deaths that women may experience in developing countries, maternal interviews provide reliable responses that can be used to estimate mortality and fertility rates in settings where vital records are incomplete or unreliable.

Rao MR, Wierzbica TF, Savarino SJ *et al.* Serologic correlates of protection against enterotoxigenic *Escherichia coli* diarrhea. *J Infect Dis* 2005; 191(4):562-70. Abstract: BACKGROUND: We conducted a nested case-control study in 397 rural Egyptian children <36 months of age to assess the correlation between serum levels of antibodies against toxin and colonization factors (CFs) and the risk of homologous enterotoxigenic *Escherichia coli* (ETEC) diarrhea. METHODS: Active case detection was performed via semiweekly home visits, and blood was obtained at 3-month intervals. After each serosurvey, case subjects were selected from children experiencing a CF antigen (CFA)/I-, CFA/II-, CFA/IV-, or heat-labile enterotoxin (LT)-ETEC diarrheal episode during the subsequent 3 months. Up to 5 control subjects per case subject were selected from children who did not experience an ETEC diarrheal episode during the corresponding interval. Serum titers of immunoglobulin G antibodies against CFA/I, coli surface antigen (CS) 3, CS6, and LT were measured by enzyme-linked immunosorbent assay. RESULTS: The distribution of serum titers of LT, CS3, and CS6 antibodies did not differ between the case and control subjects. For children <18 months of age, serum titers of CFA/I antibody were inversely related to the risk of CFA/I-ETEC diarrhea; reciprocal serum titers of CFA/I antibody > or =76 were associated with a 77% reduction in the odds of CFA/I-ETEC diarrhea. CONCLUSION: Induction of reciprocal serum titers of antibodies against CFA/I

within or above the 76-186 range should be further evaluated as a predictor for assessment of the ability of candidate vaccines to protect against CFA/I-ETEC diarrhea.

Raposo JV, Greer MH. Child abuse and neglect reporting in Hawaii: the role of dentists. *Hawaii Dent J* 2003; 34(3):5-6.

Rasmussen RC, Schermann MA, Shutske JM, Olson DK. Use of the North American guidelines for children's agricultural tasks with Hmong farm families. *J Agric Saf Health* 2003; 9(4):265-74. Abstract: This literature review synthesizes available studies on Hmong agricultural practices, patterns of childhood growth and development of Hmong children in the context of injury prevention, and potential application or adaptation of the North American Guidelines for Children's Agricultural Tasks (Lee and Marlenga, 1999) for Hmong children working in the U.S. Data from qualitative interviews, focus groups, case studies, and surveys were collected, categories were determined, and themes were identified. Field tools and practices, gender roles, and reasons for farming were examined, as well as physical and cognitive development of Hmong children and Hmong parenting techniques to describe factors related to farm task assignment of children. Current agricultural practices of Hmong in the U.S. can be described as generally small-scale operations that use mainly hand tools, manual labor, and local direct-marketing techniques. Specific practices include thinning, weeding, and hoeing; carrying tools, buckets, or baskets; setting plant supports; and watering. Hmong children appear to be given greater amounts of responsibility at earlier ages than North American children. Hmong parenting practices, as would be used in task assignment, are somewhat more authoritarian-based and lead to psychosocial skills that are more group-oriented than individual-oriented. Hmong children were found to be shorter than children in the U.S. of the same ages. This review suggests that the NAGCAT cannot be literally translated and disseminated to Hmong farming families as an injury prevention intervention. Further information is needed about what farm tasks Hmong children do and how Hmong parents assign those tasks to children.

Rau-Foster M. The dialysis facility's rights, responsibilities, and duties when there is conflict with family members. *Nephrol News Issues* 2001; 15(5):12-4. Abstract: The stressful effect that a chronic illness may have on a patient and his or her family can make the requirements of a chronic dialysis treatment program most difficult. There will be times when tensions arise between staff, patients, and family members, especially when the needs of the families and the patients are perceived as being unmet, unacknowledged, or otherwise lacking in importance to the staff.

Frustrations, if not addressed and successfully resolved, can lead to conflict and the threat of or incidences of violence. Questions that dialysis unit administrators/managers should ask when considering or revoking visitation privileges are: What are the causes and contributory factors that resulted in the unresolved issues and conflict? Did we clearly communicate our policies and procedures and the consequences for failing to follow them to those accompanying the patient? Did we fail to maintain proper boundaries with the invitee (Allowing the family members to engage in inappropriate behaviors such as threats, cursing, name-calling)? Have we attempted to resolve the issues with the family members? If so, how and what was the outcome? Did we document our actions and the family members' responses? Is the revocation of the visitation privilege the only viable option? If so, why? If not, what else could be done? What steps should be taken to minimize the disruptive effect on the patient, whose family member is being disruptive? What are the reasonable and the required steps that a facility should take to ensure that the patients are properly cared for and free from abuse and neglect? What did we learn from this situation that we could use in future situations? The uncomfortable position that Sacred Heart Hospital found itself in is a difficult one and one that many other clinics have or may experience. The focus on continuing to meet the needs of a patient while dealing with issues, such as those presented here, depicts and represents professionalism at work. Answering these questions before problems arise will help unit administrators be prepared to deal effectively with conflict at the dialysis facility. Having a plan of action in place ensures a suitable, uniform response to unacceptable situations and reduces the risk of reacting inappropriately when those situations arise.

Ray SL. Male survivors' perspectives of incest/sexual abuse. *Perspect Psychiatr Care* 2001; 37(2):49-59. Abstract: PURPOSE: To show how understanding the aftereffects of incest and other forms of sexual abuse from male survivors' perspectives may help clinicians identify males with a possible history of sexual abuse. METHODS: Audiotaped interviews with 25 male survivors described the aftereffects in eight life areas. Data were analyzed by the double-coding qualitative method. FINDINGS: Themes identified included isolation, anger, depression/suicidal feelings, addictions, or low sense of self, and distant relationships with men and women. CONCLUSIONS: Clinicians need to explore the possibility of a history of sexual abuse with males who seek treatment for addictions, suicidal ideation, depression, and chronic low self-esteem.

Rayner K, Foorman BR, Perfetti CA, Pesetsky D, Seidenberg MS. How psychological science informs the teaching of reading. *Psychol Sci* 2001; 2(2 Suppl):31-74.

Abstract: This monograph discusses research, theory, and practice relevant to how children learn to read English. After an initial overview of writing systems, the discussion summarizes research from developmental psychology on children's language competency when they enter school and on the nature of early reading development. Subsequent sections review theories of learning to read, the characteristics of children who do not learn to read (i.e., who have developmental dyslexia), research from cognitive psychology and cognitive neuroscience on skilled reading, and connectionist models of learning to read. The implications of the research findings for learning to read and teaching reading are discussed. Next, the primary methods used to teach reading (phonics and whole language) are summarized. The final section reviews laboratory and classroom studies on teaching reading. From these different sources of evidence, two inescapable conclusions emerge: (a) Mastering the alphabetic principle (that written symbols are associated with phonemes) is essential to becoming proficient in the skill of reading, and (b) methods that teach this principle directly are more effective than those that do not (especially for children who are at risk in some way for having difficulty learning to read). Using whole-language activities to supplement phonics instruction does help make reading fun and meaningful for children, but ultimately, phonics instruction is critically important because it helps beginning readers understand the alphabetic principle and learn new words. Thus, elementary-school teachers who make the alphabetic principle explicit are most effective in helping their students become skilled, independent readers.

Realmuto GM, August GJ, Egan EA. Testing the goodness-of-fit of a multifaceted preventive intervention for children at risk for conduct disorder. *Can J Psychiatry* 2004; 49(11):743-52.

Abstract: OBJECTIVE: To determine the importance of parents' global adaptive functioning as a predictor of participation rate and subsequent child social competence outcome in 3 program components of an evidence-based, multifaceted, preventive intervention for at-risk children. METHOD: Families of program children (n = 124, mean age 6.6 years at recruitment) were offered 3 program components that continued for 3 years: a 6-week summer program, a biweekly family program that included concurrent parent and child education and skills training groups, and a flexibly tailored home visitation family support program. We used structural equation modelling to test hypotheses

about the effects of parental characteristics on program attendance in each of the program components over 3 years, as well as their relation to children's social competence. RESULTS: Predictors of attendance included child IQ, socioeconomic status (SES), and single-parent status for some components but not others, depending on parents' global adaptive functioning. Predictors of child social competence outcome were mediated by attendance in specific program components and were dependent on parent global adaptive functioning. Some components contributed decisively to social competence outcomes, and others did not, despite subjects' participation. CONCLUSIONS: Common family characteristics (that is, child IQ, SES, and single-parent status) predict program attendance differently, depending on parents' global adaptive functioning. Parents' global adaptive functioning determined whether attendance in specific program components mediated children's social competence. In this preventive intervention, as in clinical practice, only knowledge of the goodness-of-fit between participant characteristics and program attributes can ensure optimum benefit.

Reboussin BA, Anthony JC. Latent class marginal regression models for modelling youthful drug involvement and its suspected influences. *Stat Med* 2001; 20(4):623-39.

Abstract: In longitudinal behavioural studies, it is common to have multiple categorical indicators for measuring a theoretical construct of interest. A latent class model is presented that accounts for the structure in a set of correlated, categorical variables measured at discrete time periods, drawing information from these variables to form a smaller number of latent classes. The dependence of the resulting latent class model parameters on suspected factors over time is simultaneously modelled using a baseline-category logistic regression model. Estimation of the model parameters is achieved using an estimating equations procedure. A motivating example is provided from a longitudinal study of suspected linkages between monitoring or supervision by parents and the occurrence of drug use behaviours in an epidemiologic sample of school-attending youths.

Reece RM. The evidence base for shaken baby syndrome: response to editorial from 106 doctors. *BMJ* 2004; 328(7451):1316-7; author reply 1317.

Rees CA. Thinking about children's attachments. *Arch Dis Child* 2005; 90(10):1058-65. Abstract: Disordered parental attachment can commit children to lives characterised by relationship difficulties, behaviour problems, educational failure, and poor self-esteem. It is a major root of trans-generational neglect and abuse and frequently underlies mental health problems, drug and alcohol addiction, homelessness, and crime. Early childhood setting of

hypothalamus-pituitary-adrenal axis function appears to contribute to these costly difficulties. More broadly, the concept of attachment can contribute to defining and managing the psychosocial dimension of routine paediatric care. The current under-representation of attachment in paediatric education, practice, and research needs to be rectified.

Regalado M, Sareen H, Inkelas M, Wissow LS, Halfon N. Parents' discipline of young children: results from the National Survey of Early Childhood Health. *Pediatrics* 2004; 113(6 Suppl):1952-8.

Abstract: OBJECTIVE: To examine the use and predictors of different discipline practices by parents of very young children using data from the 2000 National Survey of Early Childhood Health (NSECH). METHODS: NSECH is a nationally representative telephone survey of 2068 parents of young children between the ages of 4 and 35 months conducted by the National Center for Health Statistics. The survey includes questions about parents' use of 5 discipline practices: yelling, spanking, time out, toy removal, and explanations. chi2 analyses and logistic multivariate regression were used to examine associations between discipline practices and child, parent, and demographic factors. RESULTS: Among young children aged 19 to 35 months, frequent parental use of discipline strategies ranged from 26% (spanking) to 65% (taking away toy or treat), 67% (yelling), 70% (using time out), and 90% (providing explanations). In multivariate analyses, child age predicts reports of more frequent spanking and yelling, and child developmental risk is associated with increased reports of yelling. Parent frustration predicts frequent use of every discipline practice, including a greater inclination to use aversive practices. Lower parental emotional well-being is associated with reports of frequent yelling and spanking. Black ethnicity and maternal age predict more frequent spanking, and Spanish-speaking parents reported less frequent use of time out and taking away a toy. CONCLUSION: Child age and developmental risk and parents' ethnicity, emotions, and mental health are closely associated with discipline practices in the first 3 years of life. These factors are important for pediatricians to recognize in providing anticipatory guidance about discipline.

Reid MJ, Webster-Stratton C, Beauchaine TP. Parent training in head start: a comparison of program

response among African American, Asian American, Caucasian, and Hispanic mothers. *Prev Sci* 2001; 2(4):209-27.

Abstract: The effectiveness of the Incredible Years Parenting Program was evaluated in a low-income sample of Caucasian, African American, Hispanic, and Asian mothers whose children were enrolled in Head Start. Data from two prior intervention studies [Webster-Stratton (1998) *Journal of Consulting and Clinical Psychology*, 66(5), 715-730; Webster-Stratton et al. (in press) *Journal of Clinical Child Psychology*] were combined, yielding a sample of 634 families (370 Caucasian, 120 African American, 73 Asian, 71 Hispanic) across 23 Head Start centers. Centers were matched and assigned randomly to either an experimental condition (8-12 weeks of weekly 2-hr parenting classes), or a control condition (the regular Head Start Program without parenting groups). Families in both conditions were assessed using home observations of parent-child interactions and parent reports of parenting style and discipline strategies and child behavior problems in the fall (baseline) and spring (postintervention) of the children's Head Start year. Families were reassessed 1 year later. Following treatment, intervention mothers were observed to be more positive, less critical, more consistent, and more competent in their parenting than were control mothers. Additionally, children of intervention parents were observed to exhibit fewer behavior problems than were control children. Differences in treatment response across ethnic groups were few, and did not exceed the number expected by chance. Parents from all groups reported high satisfaction levels following the parenting program. Results indicate that the Incredible Years Program is accepted by and effective with diverse populations.

Reijneveld SA, van der Wal MF, Brugman E, Hira Sing RA, Verloove-Vanhorick SP. [Prevalence of parental behaviour to diminish the crying of infants that may lead to abuse]. *Ned Tijdschr Geneesk* 2004; 148(45):2227-30.

Abstract: OBJECTIVE: To estimate the prevalence of parental actions to stop infant crying that may threaten infant health, and to determine specific risk groups regarding these actions. DESIGN: Descriptive. METHOD: Before their visit to a well-baby clinic in the Netherlands, parents of 3345 infants aged 1-6 months (96.5% response) filled out an anonymous questionnaire on actions that they undertook to stop their child crying. RESULTS: At 6 months, 5.6% (95% confidence interval: 4.2-7.0%) of all the parents reported having smothered, slapped, or shaken their infant at least once because of its crying. The highest risks for detrimental parental actions were run by infants of parents from non-industrialised countries, of parents with no or only a part-time job, and of parents who had judged their infant's crying as excessive. CONCLUSION: Clinicians should be aware of the observed risk factors for abuse of young children

known to cry a lot, in order to help parents to cope with this crying.

Reimherr JP, McClellan JM. Diagnostic challenges in children and adolescents with psychotic disorders. *J Clin Psychiatry* 2004; 65 Suppl 6:5-11. Abstract: The diagnosis of psychotic disorders in children and adolescents is often complex and challenging. The symptomatic overlap between different psychotic conditions and other emotional, behavioral, and developmental disorders has led to high rates of misdiagnosis, especially at time of onset. The clinical expression and progression of diagnosable disorders are affected by maturational processes. Thus, psychotic illnesses in pediatric patients may vary from adult presentations because of developmental factors. Establishing a specific diagnosis is difficult when the differential diagnosis comprises disorders that share common symptoms and are frequently comorbid. The clinical assessment depends as much on input from parents and teachers as from the patients themselves, and there may be conflict between these different perceptions. This article reviews recent research and current concepts relating to diagnostic challenges in pediatric psychiatry.

Reinherz HZ, Paradis AD, Giaconia RM, Stashwick CK, Fitzmaurice G. Childhood and adolescent predictors of major depression in the transition to adulthood. *Am J Psychiatry* 2003; 160(12):2141-7. Abstract: OBJECTIVE: The identification of predictors of major depression in the transition to adulthood has direct application to prevention and intervention efforts designed to forestall depression in this high-risk period. The current study identified childhood and adolescent familial and behavioral-emotional factors predicting depression during this critical developmental stage. METHOD: The 354 participants were part of a single-age cohort from a predominately Caucasian working-class community whose psychosocial development has been traced prospectively since age 5. In these analyses, data collected during childhood and adolescence were related to diagnoses of major depression at ages 18-26. RESULTS: During the transition to adulthood, 82 participants (23.2%) experienced major depression. Bivariate indicators of later depression included a family history of depression or substance use disorders, family composition, and childhood family environments perceived as violent and lacking cohesiveness. Also significant were self- and mother-reported internalizing behaviors, as well as self-rated anxiety and depressive symptoms. Multivariable analyses showed family violence, family composition, internalizing problems during adolescence, and low family cohesion to be the most salient factors. CONCLUSIONS: These results highlight familial and behavioral-emotional predictors of depression that can serve as foci for identifying youth in need of intervention.

Reitman D, Currier RO, Hupp SD, Rhode PC, Murphy MA, O'Callaghan PM. Psychometric characteristics of the Parenting Scale in a head start population. *J Clin Child Psychol* 2001; 30(4):514-24. Abstract: Examined the reliability, construct, and concurrent validity of the Parenting Scale (PS), a brief instrument designed to measure dysfunctional parenting practices for parents of young children. In Study 1, 183 primarily African American mothers and their Head Start children completed the PS. The PS, which consists of 3 subscales--Laxness, Overreactivity, and Verbosity--was subjected to confirmatory factor analysis (CFA). Neither the original 3-factor structure, nor a 2-factor structure consisting of the original Laxness and Overreactivity factors, fit the data. A subsequent exploratory factor analysis yielded a 2-factor solution that was generally consistent with the Overreactivity and Laxness subscales identified by Arnold, O'Leary, Wolff, and Acker (1993). The 2-factor CFA solution was replicated with a sample of 216 similar mothers, and the 5-item Overreactivity and Laxness subscales retained internal consistencies above .70. Analysis of the convergent validity of the modified PS and its 2 subscales revealed moderate associations with measures of permissiveness, authoritarianism, involvement, and limit setting. Scores on the PS were not correlated significantly with measures of social desirability, maternal education level, or parent report of internalizing behavior problems. Concurrent validity evidence was obtained by correlating the PS with measures of parenting satisfaction and support, parenting stress, maternal depression, and measures of externalizing child behavior problems.

Rennison C, Planty M. Nonlethal intimate partner violence: examining race, gender, and income patterns. *Violence Vict* 2003; 18(4):433-43. Abstract: The correlation between race of victim and intimate partner violence (IPV) is examined. Previous research showing a relationship between Black victims and higher levels of violence were based on uni-variate examinations and often do not consider other important factors. This paper presents national estimates of IPV by victim's race using the National Crime Victimization Survey (NCVS), 1993-1999. The estimates based only on race are then disaggregated to account for the victim's gender and household income. Uni-variate findings demonstrate that victim's race is significantly related to rates of intimate partner violence. However, after controlling for both victim's gender and annual household income, the victim's race is no longer significant. The importance of understanding intimate partner violence through a person's socioeconomic status rather than race is discussed.

Renshaw DC. Pornography: reactions and reality. *Compr Ther* 2005; 31(4):251-4. Abstract: The Greek word *porne* (harlot) paired with *graphie* (picture or writing) has for centuries been used

for depiction of sexual activity from cave paintings to contemporary internet depictions, movies, and videos. Playboy-type magazines are considered "tame" today. This brief discussion will update busy physicians of all specialties as to how their patients may be using or overusing available explicit materials and will also assess the impact on the patients' current work and home adjustment.

Abstract: **CONSIDERANDO:** Que el tráfico de seres humanos y la introducción, paso y salida ilegal de éstos en diferentes países del mundo se ha convertido en un negocio que genera enormes beneficios para los traficantes y para los sindicatos del crimen organizado, que unido a los altos niveles de pobreza, desempleo y factores sociales y culturales, como la violencia contra la mujer, niños, niñas y adolescentes, la discriminación por sexo en la familia y en la comunidad, pasando por la feminización de la migración laboral en los países de origen, pueden obligar a los migrantes potenciales a recurrir a las redes del crimen;....

Resnik DB, Zeldin DC, Sharp RR. Research on environmental health interventions: ethical problems and solutions. *Account Res* 2005; 12(2):69-101. Notes: GENERAL NOTE: KIE: 60 refs. 13 fn. GENERAL NOTE: KIE: KIE Bib: human experimentation; public health Abstract: This article reviews a variety of ethical issues one must consider when conducting research on environmental health interventions on human subjects. The paper uses the Kennedy Krieger Institute lead abatement study as well as a hypothetical asthma study to discuss questions concerning benefits and risks, risk minimization, safety monitoring, the duty to warn, the duty to report, the use of control groups, informed consent, equitable subject selection, privacy, conflicts of interest, and community consultation. Research on environmental health interventions can make an important contribution to our understanding of human health and disease prevention, provided it is conducted in a manner that meets prevailing scientific, ethical, and legal standards for research on human subjects.

I. Retrospective assessment of exposure to traffic air pollution using the ExTra index in the VESTA French epidemiological study. *J Expo Anal Environ Epidemiol* 2005; 15(6):524-33.

Abstract: This study applies a traffic exhaust air dispersion model (the ExTra index) to 403 children enrolled in a French multicentric case-control study, the VESTA study (Five [V] Epidemiological Studies on Transport and Asthma). The ExTra index (previously validated by our team) was used to assess lifelong average traffic-related air pollutant (TAP) concentrations (nitrogen oxides) children in the study were exposed to in front of their living places. ExTra index took into account traffic density, topographical parameters (building height, road and pavement width), weather conditions (wind direction and strength) and background pollution levels. Topographical and traffic data were collected, using a specific questionnaire for each home, school or nursery address, attended by children. The assessment of time-weighted NO<sub>x</sub> levels in front of the children's living places highlighted significant disparities: mean ExTra index values and share attributable to proximity traffic were, respectively, 70+/-42 and 14+/-22 microg/m<sup>3</sup> NO<sub>x</sub> equivalent NO<sub>2</sub> for the 403 children in our study. Not only would this diversity not have been revealed using urban background pollution data provided by air quality networks, it would have resulted in 40% of the children being misclassified with regard to their TAP exposure by underestimating it in half of the cases and overestimating it in the other half. Such errors of classification, which are highly prejudicial in epidemiology, argue strongly for the use of an index such as the ExTra, which enables TAP exposure to be reconstructed within the framework of retrospective or prospective epidemiological studies.

Reutzel TJ, Patel R. Medication management problems reported by subscribers to a school nurse listserv. *J Sch Nurs* 2001; 17(3):131-9.

Abstract: Given the potentially serious consequences of suboptimum medication management practices in elementary and secondary schools and the fact that this topic has been subject to little empirical inquiry, the purpose of this study was to obtain a preliminary understanding of the types of medication management problems that school nurses face, as well as the strategies they use to solve those problems. An analysis of messages related to medication management that appeared on the SCHLRN-L listserv (a 1,400-member discussion group for schools nurses) was performed. All messages sent to the listserv during a 5-month period were monitored. Any discussion thread that began during this time period and addressed the management of medications was selected for possible inclusion in the study. The result was a group of 71 threads. The listserv participants described a wide array of medication management problems and suggested numerous strategies for solving them. This study shows that serious medication management problems exist in

schools and that school nurses make use of various strategies or "tricks of the trade" to handle these problems. This research highlights the need for a contribution from the pharmacy profession in this important and neglected area of drug therapy.

Rey JM, Sawyer MG, Prior MR. Similarities and differences between aggressive and delinquent children and adolescents in a national sample. *Aust N Z J Psychiatry* 2005; 39(5):366-72.

Abstract: OBJECTIVE: To examine differences in the correlates, comorbidity and use of services between aggressive and delinquent children and adolescents. METHOD: An Australian representative sample (n = 4083) of parents of children and adolescents were administered a psychiatric diagnostic interview, the Child Behaviour Checklist, and other instruments to measure service use. The characteristics of children with high scores (top 5%) in the aggressive and delinquent syndromes or both were then examined. RESULTS: The proportion of aggressive children decreased with increasing age while that of delinquents increased. The aggressive group was specifically associated with the impulsive-hyperactive subtype of attention deficit hyperactivity disorder (ADHD) (OR = 12.63; 95% CI = 5.97-26.74). Comorbidity between ADHD, aggression and delinquency was less frequent among adolescents than in children, with the exception of the inattentive subtype in which comorbidity was higher. Both aggressive and delinquent groups had a considerable overlap with conduct disorder. Aggressive and delinquent youths used services more often, but parents perceived aggressive children as more in need of help than delinquent ones. Living in a sole parent family was specifically associated with the delinquent group (OR = 3.34; 95% CI = 2.25-4.96). CONCLUSIONS: The results suggest that these empirically derived syndromes while sharing many features also differ in important ways, highlighting the need for further convergence between categorical and dimensional classifications. Their differential association with the subtypes of ADHD requires further examination and may help to understand the relationship between ADHD and conduct problems. The importance of aggressive behaviour in children should not be underestimated since it is associated with significant psychopathology, parental distress and use of services.

Reyes H, Perez-Cuevas R, Sandoval A *et al.* The family as a determinant of stunting in children living in conditions of extreme poverty: a case-control study. *BMC Public Health* 2004; 4:57.

Abstract: BACKGROUND: Malnutrition in children can be a consequence of unfavourable socioeconomic conditions. However, some families maintain adequate nutritional status in their children despite living in poverty. The aim of this study was to ascertain whether family-related factors are determinants of stunting in young Mexican children living in extreme poverty, and

whether these factors differ between rural or urban contexts. **METHODS:** A case-control study was conducted in one rural and one urban extreme poverty level areas in Mexico. Cases comprised stunted children aged between 6 and 23 months. Controls were well-nourished children. Independent variables were defined in five dimensions: family characteristics; family income; household allocation of resources and family organisation; social networks; and child health care. Information was collected from 108 cases and 139 controls in the rural area and from 198 cases and 211 controls in the urban area. Statistical analysis was carried out separately for each area; unconditional multiple logistic regression analyses were performed to obtain the best explanatory model for stunting. **RESULTS:** In the rural area, a greater risk of stunting was associated with father's occupation as farmer and the presence of family networks for child care. The greatest protective effect was found in children cared for exclusively by their mothers. In the urban area, risk factors for stunting were father with unstable job, presence of small social networks, low rate of attendance to the Well Child Program activities, breast-feeding longer than six months, and two variables within the family characteristics dimension (longer duration of parents' union and migration from rural to urban area). **CONCLUSIONS:** This study suggests the influence of the family on the nutritional status of children under two years of age living in extreme poverty areas. Factors associated with stunting were different in rural and urban communities. Therefore, developing and implementing health programs to tackle malnutrition should take into account such differences that are consequence of the social, economic, and cultural contexts in which the family lives.

Ribeiro MA, Ferriani MG, Reis JN. [Sexual abuse of children and adolescents: characteristics of sexual victimization in family relations]. *Cad Saude Publica* 2004; 20(2):456-64.  
 Abstract: This study analyzes the characteristics of sexual abuse committed within the family against age groups classified according to the Brazilian Statute for Children and Adolescents (the prevailing legislation on matters pertaining to minors) and treated at the Reference Center for Children and Adolescents and the Guardianship Councils in Ribeirao Preto, Sao Paulo State, Brazil, from 1995 to 2000. Some 234 abuses were identified, committed by 217 aggressors, against 210 families and a total of 226 victims. A total of 131 children (48.7%) and 95 adolescents (41.2%), predominantly females, were victimized. Children ranging from 10 to 12 years were the most frequently abused (19.5%), as well as adolescents from 12 to 14 years old (17.3%). The majority of the victims live in families with 3 (19.9%) or 4 children (17.7%), and the firstborn are the most frequently abused (33.6%). The majority of aggressors who acted alone victimized only one individual (86.7%). Fathers (34.2%) and

stepfathers (30.3%) were the most frequent aggressors, with the former victimizing more children (19.7%) and the latter adolescents (17.1%).

Ribisl KM, Lee RE, Henriksen L, Haladjian HH. A content analysis of Web sites promoting smoking culture and lifestyle. *Health Educ Behav* 2003; 30(1):64-78.  
 Abstract: The present study examined smoking culture and lifestyle Web sites listed on Yahoo!, a popular Internet search catalog, to determine whether the sites were easily accessible to youth, featured age or health warnings, and mentioned specific tobacco brands. A content analysis of photographs on these sites assessed the demographics of individuals depicted and the amount of smoking and nudity in the photographs. The sample included 30 Web sites, all of which were accessible to youth and did not require age verification services to enter them. Cigarette brand names were mentioned in writing on 35% of the sites, and brand images were present on 24% of the sites. Nearly all of the photographs (95%) depicted smoking, 92% featured women, and 7% contained partial or full nudity. These results underscore the need for greater research and monitoring of smoking-related Internet content by health educators and tobacco control advocates.

Ricci FL. The Italian national telemedicine programme. *J Telemed Telecare* 2002; 8(2):72-80.  
 Abstract: The Italian national telemedicine programme included a broad range of research projects, but they all served the common purpose of bringing about improvements in health-care management and performance. The programme consisted of seven projects, each of which had specific research and training objectives, and a three-year duration. The systems developed in the course of the programme were not experimental prototypes: they were intended to be pre-commercial systems. The functional and clinical merits of the products and systems developed were evaluated, and their costs and benefits measured with reference to those already in use. The seven projects were completed in 1999. The Italian Ministry of Universities, Research and Technology granted research funds totalling 50,000,000 Euros for the whole programme. While the results of the research were promising, successful projects alone are not sufficient to reduce costs in health-care. Indeed, far more money can be saved simply by encouraging the uptake on a larger scale of many technologies and practices that already exist.

Ricciardi C, Guastadisegni C. Environmental inequities and low birth weight. *Ann Ist Super Sanita* 2003; 39(2):229-34.  
 Abstract: The effects of environmental exposures to toxic agents, are related to different levels of exposure, genetic and biological susceptibility, risk perception and socioeconomic status (SES). In the present study

we suggest that environmental influences on human reproduction should include investigations on SES, that can play an important role in embryo-foetal development. Low birth weight (LBW) is a risk factor for developing in adulthood coronary heart disease, hypertension and type 2 diabetes. Maternal nutritional status and other hypothesis could explain LBW, however, environmental exposures are recognised as essential risk factors. Different studies evidenced an increased risk of LBW in relation to increased environmental air levels of particulate matter, carbon monoxide, and sulphur dioxide. Considering different risk possibilities and different risk perceptions, there is a need of a different scientific approach in which the scientific knowledge is connected with ethical and socioeconomic factors, for risk management, in order to overcome the environmental health inequities based on social context.

Riddell-Heaney J, Allott M. Different cultures but equal needs. *Prof Nurse* 2003; 18(5):248-9. Abstract: Many health professionals deal with issues of child protection on a regular or occasional basis, so they not only need a good understanding of their duties but also an awareness of cultural issues.

Ridgway D. Court-mediated disputes between physicians and families over the medical care of children. *Arch Pediatr Adolesc Med* 2004; 158(9):891-6. Abstract: OBJECTIVE: To describe the judiciary's approach to parent-physician disputes over the care of sick children. DATA SOURCES: Court publications. STUDY SELECTION: Fifty parent-physician disagreements over the care of children led to physician requests for court intervention and resulted in judicial opinions published by the court. The opinions describe 66 children from 20 states. DATA SYNTHESIS: Physicians prevailed at the initial decision in 44 (88%) of the 50 disputes and at the final decision in 40 disputes (80%). Physicians were more likely to prevail in religion-based disputes than in other cases (27 of 30 vs 13 of 20;  $P < .03$ ), but they were less likely to prevail in disputes concerning life-threatening or potentially disabling conditions (23 of 31 vs 17 of 19;  $P < .19$ ). Courts acknowledged the pediatric patients' views in only 10 of the disputes (9 of the 19 cases involving adolescents and 1 of the 31 cases involving children younger than 12 years). For most courts, the petitioning physicians provided the only source of scientific information. CONCLUSIONS: Published court opinions create precedents for future decisions

and provide insight into the consequences of seeking court intervention for the physician who encounters parental refusal of care.

Ridgway DM, White SA, Kimber RM, Nicholson ML. Current practices of donor pancreas allocation in the UK: future implications for pancreas and islet transplantation. *Transpl Int* 2005; 18(7):828-34. Abstract: Recent refinements in technique mean islet cell transplantation offers the chance of a cure to an increasing patient cohort with diabetes. Such developments put pressure upon the scarce resource of donor organs, with potential competition between the modalities of cellular and solid organ transplantation. This questionnaire based study examines current patterns of donor pancreas procurement and use. Reasons for non procurement are studied together with the attitudes of transplant professionals to pancreas allocation. The minority of potentially useful pancreata are currently made available to either whole pancreas or islet transplant programs. Whilst professionals appreciate the role of each modality, there is a need to define criteria for pancreas allocation to avoid under use of donor organs.

Riedy CA, Weinstein P, Milgrom P, Bruss M. An ethnographic study for understanding children's oral health in a multicultural community. *Int Dent J* 2001; 51(4):305-12.

Abstract: OBJECTIVE: To provide guidance for a public health intervention in a high caries rate multicultural population by understanding cultural issues surrounding children's oral health. METHOD: Seven community focus groups were conducted with five ethnic populations (Chamorro, Filipino, Carolinian, Pohnpean, and Chuukese) living on the island of Saipan, Commonwealth of the Northern Mariana Islands, USA. Participants were asked questions about their beliefs, attitudes, knowledge, and care practices regarding issues around children's oral health. RESULTS: Analysis consisted of a content review of participants' responses within two targeted areas: past and current attitudes and health beliefs, and behaviours impacting risk of developing disease. Both the lack of value of baby teeth and negative parental experiences are factors underlying health beliefs and behaviours. Although some differences in beliefs and practices existed across cultural groups, most women were interested in learning about new preventive strategies to reduce dental disease. Several new mothers reported that they actively sought out parenting information during their initial pregnancy. CONCLUSIONS: Aversive parental experience and disregard for primary dentition were identified as serious obstacles to be addressed in order for any new programme to be effective. Despite these obstacles, new mothers were open to information and strategies to reduce the prevalence of early childhood caries.

Riem S. [Sexual abuse--neglect--violence. Accordingly you diagnose child abuse]. *MMW Fortschr Med* 2002; 144(8):16.

Rigby MJ, Kohler LI, Blair ME, Metchler R. Child health indicators for Europe: a priority for a caring society. *Eur J Public Health* 2003; 13(3 Suppl):38-46. Abstract: BACKGROUND: Measurement of children's health is important for two reasons: first, because young people are citizens in their own right, yet largely unable to act as self-advocates, particularly at the population level; and second, because their health determines the health of the future population. Indicators based on measurements of child health are important for identifying progress, problems and priorities, changes over time, and newly emergent issues. The European Community Health Monitoring Programme (HMP) is a comprehensive programme to develop and implement a set of national-level indicators. The Child Health Indicators of Life and Development (CHILD) project is the only population group-specific project, seeking to determine a holistic set of measures. METHODS: The project endeavoured to address all aspects of child health and its determinants, balancing positive and negative aspects. It undertook a structured search of published evidence to seek to identify, and validate, indicators of health and illness, health determinants and challenges to health, quality of healthcare support and health-promoting national policies. A systematic approach was used in identifying valid indicators, and in assembling a balanced composite list. All ages from infancy to adolescence were covered. RESULTS: The project's final report identifies 38 core desirable national indicators, citing purpose and evidence for each. Of equal importance, it also identifies 17 key child health topics on which further research work is needed in order to identify and validate indicators appropriate across different national settings.

Riggs SA, Jacobvitz D. Expectant parents' representations of early attachment relationships: associations with mental health and family history. *J Consult Clin Psychol* 2002; 70(1):195-204. Abstract: The association between adult representations of early attachment relationships and history of individual and family mental health was examined in a sample of 233 expectant mothers and fathers. As predicted, security of attachment was linked to mental health. Parents classified as Preoccupied were more likely than other parents to report suicidal ideation. Whereas parents classified as Unresolved more often reported suicidal ideation, emotional distress, and substance abuse. With respect to family history. Unresolved and Preoccupied attachment classifications were significantly related to child abuse involving a relative and parental separation or divorce. These findings support theoretical conceptualizations regarding the link between adult attachment and mental health in middle-class American adults.

Riley EP, Mattson SN, Li TK *et al.* Neurobehavioral consequences of prenatal alcohol exposure: an international perspective. *Alcohol Clin Exp Res* 2003; 27(2):362-73.

Abstract: This article represents the proceedings of a symposium at the 2002 Research Society on Alcoholism/International Society for Biomedical Research on Alcoholism meeting in San Francisco, CA. The organizers were Edward P. Riley and Sarah N. Mattson, and the chairperson was Edward P. Riley. The presentations were (1) Neurobehavioral deficits in alcohol-exposed South African infants: preliminary findings, by Sandra W. Jacobson, Christopher D. Molteno, Denis Viljoen, and Joseph L. Jacobson; (2) A pilot study of classroom intervention for learners with fetal alcohol syndrome in South Africa, by Colleen Adnams, M. W. Rossouw, M. D. Perold, P. W. Kodituwakku, and W. Kalberg; (3) Differential effects of prenatal alcohol exposure on fluid versus crystallized intelligence, by P. W. Kodituwakku, W. Kalberg, L. Robinson, and P. A. May; (4) Neurobehavioral outcomes of prenatal alcohol exposure: early identification of alcohol effects, by Claire D. Coles; (5) Fetal alcohol syndrome in Moscow, Russia: neuropsychology test performance, by Sarah N. Mattson, E. P. Riley, A. Matveeva, and G. Marintcheva; and (6) Long-term follow-up of Finnish children exposed to alcohol in utero in various durations, by Marit I. Korkman and I. Autti-Ramo. The discussant was Ting-Kai Li.

Ripamonti C, Bianchi M. The use of methadone for cancer pain. *Hematol Oncol Clin North Am* 2002; 16(3):543-55.

Abstract: Methadone is not a new analgesic drug [69]. Several studies have demonstrated that methadone is a valid alternative to morphine, hydromorphone, and fentanyl for the treatment of cancer-related pain, and extensive reviews on the subject have been published in recent years [10,23,25,64,70,71]. Most people involved in pain therapy, however, are not well informed about the properties of methadone. The authors believe that the low cost of methadone paradoxically contributes to the limited knowledge of its characteristics and to the restricted therapeutic use of this drug. The low cost of methadone means there is little financial incentive for pharmaceutical companies to invest in research or to disseminate scientific information. Unfortunately, the lack of scientific information from pharmaceutical companies frequently results in a lack of knowledge on the part of physicians. Unless the existing approach changes, both culturally and politically, ignorance about methadone will persist among medical experts. The low cost of methadone, rather than being an advantage, will result in the limited exploitation of an effective drug.

Ripley A. Inside the church's closet. *Time* 2002; 159(20):60-4.

Ritchie A. Nutrition education and promotion in primary schools. *Aust J Holist Nurs* 2001; 8(2):39-44. Abstract: Health promotion with school-age children can enhance knowledge about nutrition and change eating habits when health workers, schools, and communities work together for a common goal. A range of options need to be considered when designing an effective and appropriate school-based program.

Ritchie LD, Welk G, Styne D, Gerstein DE, Crawford PB. Family environment and pediatric overweight: what is a parent to do? *J Am Diet Assoc* 2005; 105(5 Suppl 1):S70-9.

Abstract: Although the causes of pediatric overweight are many and the levels of intervention required to prevent overweight in children extend from the child's immediate environment to the larger societal level, one critical intervention target is the parent. Scientific evidence points to specific dietary and physical activity/inactivity behaviors that families can adopt to encourage healthful weight status. Dietary recommendations include providing children with ample access to nutrient-dense foods and beverages and high-fiber foods, both at meals and snack times, reducing children's access to high-calorie, nutrient-poor beverages and foods both when eating at home and at restaurants, avoiding excessive food restriction or use of food as a reward, and encouraging children to eat breakfast on a daily basis. Physical activity recommendations include providing opportunities and encouragement for children to be physically active while reducing children's television and video game time. Parental modeling of healthful eating and physical activity practices is recommended to reinforce these patterns in youth. Dietetics professionals, physicians, and other health care professionals can assist parents in their efforts to prevent pediatric overweight by providing information and supporting these key behaviors, while working to create environments that support healthful lifestyle changes.

Rivera HP. Developing collaborations between child welfare agencies and Latino communities. *Child Welfare* 2002; 81(2):371-84.

Abstract: Collaborative efforts to achieve permanency planning and family stability for all children in the child welfare system are increasing. As Latino children and families constitute the fastest growing ethnic group in the child welfare system, it is important to understand how to develop culturally sensitive collaborations with their communities. The purpose of this article is to suggest helpful guidelines for developing collaborations between child welfare agencies and Latino communities.

Rivera-Rivera L, Allen B, Thrasher JF *et al*. Intra-familial physical violence among Mexican and Egyptian youth. *Rev Saude Publica* 2005; 39(5):709-15. Abstract: OBJECTIVE: To determine the prevalence of

experiencing intra-familial violence among Mexican and Egyptian youth and to describe its associated risk factors. METHODS: Data from questionnaires applied to 12,862 Mexican and 5,662 Egyptian youth, aged 10 to 19, who attended public schools were analyzed. Bivariate and logistic regression analysis were used to determine the relationship between socio-demographics, the experience of intra-familial violence and violence perpetration. RESULTS: The prevalence of having experienced intra-familial violence was comparable across the Mexican and Egyptian populations (14% and 17%, respectively). In Mexico, young men were more likely to have experienced such violence (OR=2.36) than women, whereas in Egypt, young women were at slightly greater risk than young men (OR=1.25). Older age, male gender and urban residence were independent correlates of experiencing intra-familial violence among Mexican youth. For Egyptian adolescents, in contrast, younger age, female gender and having non-married parents were independent correlates of victimization. Intra-familial violence victims were also more likely than non-victims to perpetrate violence (Mexico: OR=13.13; Egypt: OR=6.58). CONCLUSIONS: Mexican and Egyptian youth experienced intra-familial violence at a relatively low prevalence when compared with youth of other countries. A strong association was found between experiencing intra-familial violence and perpetrating violence.

Robbins H, Hundley V, Osman LM. Minor illness education for parents of young children. *J Adv Nurs* 2003; 44(3):238-47.

Abstract: BACKGROUND: A number of previous studies on minor illness have concentrated on nurse-led clinics and the role of nurse practitioners. This study examines the effect of a minor illness education programme which aimed to increase parents' confidence and knowledge in managing childhood illnesses. AIM: The primary aim of this study was to evaluate the effectiveness of a home visit and booklet in providing education to parents about minor infant illnesses. DESIGN: A randomized controlled trial was conducted. The intervention involved a home visit to discuss parents' concerns and provide advice and information, and a booklet advising parents what to do and when to consult about infant illnesses. METHOD: A total of 120 parents of 6 week old babies were identified over a 6 month period, using health visitors' caseloads, and randomized to an intervention group (60), that received a visit and a booklet, or a control group (60) that received standard care. Groups were

compared on entry to the study and at 7 months, in terms of parental knowledge and confidence about childhood illnesses, the intended use of home care activities, intention to consult professionals and actual use of health services. Data were collected by self-completed questionnaire and case note review. FINDINGS: The educational intervention resulted in a reduction in visits to the child health clinic but had little effect on use of other services. Parents in the intervention group showed a general trend towards greater certainty about the home care options they would choose, and a reduction in intention to consult a doctor. However, they also indicated a feeling of reduced confidence and knowledge. CONCLUSION: The trial showed no effect on use of services but did demonstrate reduction in parents' intentions to consult a doctor, which appeared to be because of increased certainty about home care. However, it is of concern that they indicated feeling less confident and knowledgeable. It is not possible to clarify whether this represented anxiety that was constructive, enhancing decision-making or was destructive. Further work into the role of education in parental decision-making, anxiety levels and enhancement of confidence is required.

Robertson AS, Rivara FP, Ebel BE, Lymp JF, Christakis DA. Validation of parent self reported home safety practices. *Inj Prev* 2005; 11(4):209-12. Abstract: OBJECTIVES: To evaluate the validity of parents' self reported home safety practices concerning smoke detectors, bike helmets, car seats, and water heater temperature. SETTING: Parents of children 12 years old and under whose child had made at least one visit to a study clinic in the years 2000-2003. METHODS: As part of a randomized controlled trial to improve patient provider communication and preventive practices, parents' responses to telephone interview were compared with observations of safety practices during a home visit. Home visits were completed within nine weeks of the telephone interview. Parents were not told that the visit was part of a validation study and home visit observers were unaware of the interview responses. The authors calculated sensitivities, specificities, positive and negative predictive values, and their corresponding confidence intervals. RESULTS: Sensitivity (0.78 to 0.98) and positive predictive values (0.75 to 1.00) were high for all items. Specificities and negative predictive values were more variable and the highest estimates (specificity 0.95 to 1.00, negative predictive value 0.95 to 0.97) were for car seat types. CONCLUSIONS: The results suggest that parent self report practice of certain injury prevention behaviors (owning a car seat, hot water temperatures) is reliable, whereas self reports on other practices (working smoke detectors, properly fitting bike helmets) may be overstated.

Robertson CL, Bell MJ, Kochanek PM *et al.* Increased adenosine in cerebrospinal fluid after severe traumatic

brain injury in infants and children: association with severity of injury and excitotoxicity. *Crit Care Med* 2001; 29(12):2287-93.

Abstract: OBJECTIVES: To measure adenosine concentration in the cerebrospinal fluid of infants and children after severe traumatic brain injury and to evaluate the contribution of patient age, Glasgow Coma Scale score, mechanism of injury, Glasgow Outcome Score, and time after injury to cerebrospinal fluid adenosine concentrations. To evaluate the relationship between cerebrospinal fluid adenosine and glutamate concentrations in this population. DESIGN: Prospective survey. SETTING: Pediatric intensive care unit in a university-based children's hospital. PATIENTS: Twenty-seven critically ill infants and children who had severe traumatic brain injury (Glasgow Coma Scale < 8), who required placement of an intraventricular catheter and drainage of cerebrospinal fluid as part of their neurointensive care. INTERVENTIONS: None. MEASUREMENTS AND MAIN RESULTS: Patients ranged in age from 2 months to 14 yrs. Cerebrospinal fluid samples (n = 304) were collected from 27 patients during the first 7 days after traumatic brain injury. Control cerebrospinal fluid samples were obtained from lumbar puncture on 21 infants and children without traumatic brain injury or meningitis. Adenosine concentration was measured by using high-pressure liquid chromatography. Adenosine concentration was increased markedly in cerebrospinal fluid of children after traumatic brain injury vs. controls (p < .001). The increase in cerebrospinal fluid adenosine was independently associated with Glasgow Coma Scale < or = 4 vs. > 4 and time after injury (both p < .005). Cerebrospinal fluid adenosine concentration was not independently associated with either age (< or = 4 vs. > 4 yrs), mechanism of injury (abuse vs. other), or Glasgow Outcome Score (good/moderately disabled vs. severely disabled, vegetative, or dead). Of the 27 patients studied, 18 had cerebrospinal fluid glutamate concentration previously quantified by high-pressure liquid chromatography. There was a strong association between increases in cerebrospinal fluid adenosine and glutamate concentrations (p < .005) after injury. CONCLUSIONS: Cerebrospinal fluid adenosine concentration is increased in a time- and severity-dependent manner in infants and children after severe head injury. The association between cerebrospinal fluid adenosine and glutamate concentrations may reflect an endogenous attempt at neuroprotection against excitotoxicity after severe traumatic brain injury.

Robson A, Beattie A. Diana Children's Community Service and service co-ordination. *Child Care Health Dev* 2004; 30(3):233-9; discussion 241. Abstract: BACKGROUND: The Diana Service and the multi-agency service co-ordination project in Leicester, Leicestershire and Rutland were established to address the needs of children with complex needs. The Mary Seacole Research Centre at De Montfort University in Leicester evaluated the services over a period of approximately 1 year. METHODS: Predominantly qualitative methods were used. Different approaches to sampling were employed and in both cases a range of data collection tools were utilized, e.g. written questionnaires, personal face-to-face interviews, focus group, non-participant observation and information from professional records. RESULTS: The findings suggest that both services are making a considerable contribution towards ensuring that effective collaboration within and between services occurs. This makes a real difference to the lives of children and families.

Roche B, Cowley S, Salt N *et al.* Reassurance or judgement? Parents' views on the delivery of child health surveillance programmes. *Fam Pract* 2005; 22(5):507-12. Abstract: BACKGROUND: The first year of a child's life is a crucial time for child development. Current guidance about child health surveillance and health promotion programmes emphasises a partnership approach between health professionals and parents when it comes to child health care. Parents' voices have been largely absent from discussions about local child health programmes. For partnership working to be effective and for local services to be able to evolve effectively parents' views are vital. OBJECTIVES: This study aimed to explore parents' views on the child health surveillance and health promotion programmes offered during the first year of their child's life. The study aimed to be consumer-led through the involvement of lead parents in all stages of the research process. METHODS: This study employed a qualitative methodology of focus groups and individual interviews. 35 participants were drawn from three general practices using a snowball sampling technique. Eligibility was determined as parents with a child under the age of one year or expecting a baby within the study timescale and registered at one of the 3 general practices. Focus groups were led by three 'parent-researchers' and individual interviews were conducted by a researcher. All focus groups and

interviews were tape-recorded, transcribed and analysed using Atlas.Ti. RESULTS: Several main themes were identified in this study. Firstly, when discussing scheduled health checks for children under one year of age parents expressed more positive feelings for the eight-week check which was seen to be comprehensive and informative rather than the eight-month check which was viewed as bureaucratic and less reassuring. Secondly, parents clearly articulated a need for reassurance and support from health professionals involved in child health surveillance and health promotion programmes. Thirdly, a crucial professional in the delivery of these programmes was the health visitor. Whilst parents expressed support for the concept of health visitors some health visitors were seen as bureaucratic and as making judgements of need based on socio-economic factors. Finally, some parents spoke of feeling excluded from accessing support as they were deemed not to be 'in need'. CONCLUSIONS: Wider concepts of partnership working between health professionals and parents, and, needs assessment are important to this study. Crucial elements of the partnership appear to be missing and this coupled with needs assessments that leave parents feeling excluded mean that there are discrepancies between expectations and experiences of parents. These issues require consideration in order to improve services and experiences.

Rodgers CS, Lang AJ, Laffaye C, Satz LE, Dresselhaus TR, Stein MB. The impact of individual forms of childhood maltreatment on health behavior. *Child Abuse Negl* 2004; 28(5):575-86. Abstract: OBJECTIVE: This study examines the unique contribution of five types of maltreatment (sexual abuse, physical abuse, emotional abuse, physical neglect, emotional neglect) to adult health behaviors as well as the additive impact of exposure to different types of childhood maltreatment. METHOD: Two hundred and twenty-one women recruited from a VA primary care clinic completed questionnaires assessing exposure to childhood trauma and adult health behaviors. Regression models were used to test the relationship between childhood maltreatment and adult health behaviors. RESULTS: Sexual and physical abuse appear to predict a number of adverse outcomes; when other types of maltreatment are controlled, however, sexual abuse and physical abuse do not predict as many poor outcomes. In addition, sexual, physical, and emotional abuse and emotional neglect in childhood were all related to different adult health behaviors. The more types of childhood maltreatment participants were exposed to the more likely they were to have problems with substance use and risky sexual behaviors in adulthood. IMPLICATIONS: The results indicate that it is important to assess a broad maltreatment history rather than trying to relate specific types of abuse to particular adverse health behaviors or health outcomes.

Rodrigues SS, de Almeida MD. Portuguese household food availability in 1990 and 1995. *Public Health Nutr* 2001; 4(5B):1167-71.

Abstract: OBJECTIVE: To examine the changes in Portuguese household food availability from 1990 to 1995. DESIGN: Using the DATA Food NETWORKING (DAFNE) classification scheme for nutritional and socio-economic variables, data from the Portuguese Household Budget Surveys collected in 1989/90 and 1994/95 were analysed. The mean availability (quantity person(-1) day(-1)) for the total population, by locality and by level of education of the household head, was computed for each of the main food and beverage groups. SETTING: Portugal, 1989 to 1995. RESULTS: Although still among one of the countries with high availability of cereals, pulses, fish and seafood and olive oil, Portugal is gradually moving away from the traditional 'Mediterranean diet'. Between 1989 and 1995, the availability of complex carbohydrates and olive oil was reduced, while the availability of protein-supplying food groups increased. Considerable disparities can be observed by locality and by the level of education of the household head. Households in urban areas and of higher socio-economic status are the main actors of the changes in 'traditional' food habits. CONCLUSION: Although these findings are based on household food availability rather than consumption, they indicate the direction of the changes taking place in the Portuguese diet and can be used effectively by agriculture specialists, nutrition experts and policy makers.

Rodriguez GM, Luis MA. [Descriptive study of drug use among adolescents in higher middle education in Monterrey, Nueva Leon, Mexico]. *Rev Lat Am Enfermagem* 2004; 12 Spec No:391-7. Abstract: We aimed to establish the consumption profile of licit and illicit drugs, consumption patterns and strategies for coping and resisting alcohol, tobacco and other drugs among adolescents in higher middle education. This study was based on concepts developed by specialized authors and considered the subject's behavioral, psychological and normative characteristics. The non-probabilistic sample consisted of 325 adolescents. Results indicated that 67%, 65% and 7% of the adolescents, respectively, accepted they had already used alcohol, tobacco and marijuana at some time in their life and that 33%, 38% and 3%, respectively, had used these same substances over the last month; 65% consider most of their colleagues have used these substances; 56% had to reject an offer to consume alcohol, 64% tobacco and 51% marijuana over the last month. On the basis of these findings, we recommend the implementation of a prevention program aimed at supporting the adolescent's resources to resist pressure towards consumption.

Rodriguez Holguin S, Corral M, Cadaveira F. Middle-latency auditory evoked potentials in children at high risk for alcoholism. *Neurophysiol Clin* 2001; 31(1):40-

7.

Abstract: PURPOSE: In the course of a high-risk study for alcoholism, the middle-latency auditory evoked potentials (MAEPs) of children of alcoholics were explored. MATERIAL AND METHODS: A series of auditory clicks (0.1 ms, 60 dB SL, 1.1/s) were used to record the Pa and Pb peaks of the MAEPs in 15 children of alcoholics with a multigenerational family history of alcoholism, and 17 control subjects, ranging from 10 to 14 years of age. RESULTS: The latency of Pb was shorter in the high-risk than in the control group, and there was also a significant risk group by age interaction on Pa latency. The amplitude of Pa was smaller in the children of alcoholics. CONCLUSIONS: The characteristics of the MAEPs of the high-risk subjects did not match the pattern of abnormalities previously observed in chronic alcoholics, which are supposed to be a consequence of the neurotoxic effects of ethanol. Nonetheless, the results showed significant differences in MAEPs between children of alcoholics and controls, pointing to an anomalous pattern of information transmission from thalamus to cortex that should be further analyzed using larger samples in a broader age range.

Rodriguez J, De La Torre A, Miranda CT. [Mental health in situations of armed conflict]. *Biomedica* 2002; 22 Suppl

2:337-46.

Abstract: Mental health is a serious problem in Latin America where many communities have been directly affected by armed conflict, communities in which large population groups have been displaced or have sought refuge. Research studies and epidemiological statistics are summarized to emphasize the psychosocial consequences of traumatic events associated with armed conflict. In addition to specific psychological disorders, other more generalized are considered such as fear, affliction, diseases, social disorder, violence and psychoactive substance consumption. Finally, the main points of a mental health plan for emergency situations are described which include the following: (1) preliminary diagnosis, (2) increase, decentralize and strengthen mental health public services, (3) psychosocial attention to the prevailing disorders--with emphasis on childhood problems, (4) initiate training and use of non-specialized personnel, and (5) identification of special needs requiring attention by psychologists and psychiatrists. Other aspects emphasized were community education, training, social communication, community organization, social participation, interinstitutional coordination, flexibility, sustainability, and specific actions in accordance with local needs.

Roe KV. Relationship between male infants' vocal responses to mother and stranger at three months and self-reported academic attainment and adjustment measures in adulthood. *Psychol Rep* 2001; 89(2):255-8. Abstract: This study explored whether 3-mo.-old male infants' differential vocal response to mother vs a

female stranger, which has been related to cognitive and academic functioning up to 12 years of age, is also related to adult development. Of the 12 subjects who had been seen from infancy through 12 years, 10 were located at Ages 21 and 28 years and were asked about their high school grade point average, scores on the SAT, years of schooling, emotional adjustment, substance abuse, and if they were in a stable relationship by the age 28. Responses showed 3-mo.-olds' differential vocal response was related positively to high school grade point average, scores on the SAT, years of completed education by age 28, and stability of relationship by age 28, and negatively related to substance abuse. No relationship was found between differential vocal response and reported emotional problems. Results suggest that early infant social interactions may be linked to adult development or adjustment.

Rogala C, Tyden T. Does pornography influence young women's sexual behavior? *Womens Health Issues* 2003; 13(1):39-43.

Abstract: Young women (n = 1,000), visiting a family planning clinic in Stockholm, Sweden, answered a questionnaire about their sexual behavior and if they had seen pornography. Four out of five had consumed pornography, and one-third of these believed that pornography had impacted their sexual behavior. As many as 47% had experienced anal intercourse, which was significantly more common among older women (51%) than among teenagers (31%). The majority valued anal intercourse as a negative experience. As the use of a condom was low (40%) when having anal intercourse, the consequences for the spread of sexually transmitted diseases should be considered.

Rogde S, Hougen HP, Poulsen K. Asphyxial homicide in two Scandinavian capitals. *Am J Forensic Med Pathol* 2001; 22(2):128-33.

Abstract: In the Oslo and Copenhagen capital areas, 94 asphyxial homicides were committed in the 10-year period 1985-1994, accounting for 22% of all homicides in that period. Sixty-nine (73%) of the asphyxia victims were female. The most common method of asphyxiation was manual strangulation. Seventeen (18%) of the victims were below the age of 10, accounting for 59% of all homicides in that age group. Whereas 38% of the female victims were killed by their spouse, this was the case for only one male victim. The motive was not known in a great proportion of cases. Fifty-seven percent of the victims had been subjected to additional violence, and in this respect there was no difference between the sexes. In 12 of the cases the offender was female; in 9 such cases the victim was her offspring. More than half of the victims had no blood alcohol. When disregarding the victims less than 10 years of age, 33% of the male and 49% of the female victims had no blood alcohol. The crime scene was the victim's domicile among 72% of female and 52% of male victims. Forty-two percent of

the female and 11% of the male victims above the age of 10 years were married or cohabitant.

Rogers EL. Community partnering and coalition development: finding solutions to oral health care problems together. *J Dent Educ* 2001; 65(9):892-5.

Roggin KK, Chwals WJ, Tracy TF. Institutional Review Board approval for prospective experimental studies on infants and children. *J Pediatr Surg* 2001; 36(1):205-8.

Abstract: **BACKGROUND/PURPOSE:** The Declaration of Helsinki requires Institutional Review Board (IRB) approval for experimental studies on human subjects. The authors questioned whether published prospective surgical experimental studies document IRB approval for infants and children. **METHODS:** Prospective studies were identified in 5 surgical and 2 major pediatric journals from 1997 through 1999. Documentation of IRB approval was recorded. Results were analyzed using Pearson chi(2) tests and a multivariate regression model. Statistical significance was defined as P less than .05. **RESULTS:** A total of 149 prospective experimental studies on pediatric subjects were evaluated; the majority being interventional or therapeutic studies (105 of 149). More than 75% were from academic medical centers (125 of 149), grant-supported (110 of 149), and appeared in surgical journals (110 of 149). Slightly less than 25% of studies (40 of 149) documented IRB approval. Observational studies, grant support, and publication in nonsurgical journals all correlated positively with IRB approval and were statistically significant variables (P<.001, P<.001, P<.001, respectively). Interventional or therapeutic, institutionally or privately-funded studies found in surgical journals were most likely to avoid IRB documentation (P<.001). **CONCLUSIONS:** The majority of prospective pediatric studies in the surgical journals omit IRB documentation. Strict requirements for specific IRB approval and documentation in compliance with the Declaration of Helsinki would allow higher ethical standards for the clinical investigation of infants and children.

Rogowski JA, Staiger DO, Horbar JD. Variations in the quality of care for very-low-birthweight infants: implications for policy. *Health Aff (Millwood)* 2004; 23(5):88-97.

Abstract: Much of the decline in childhood mortality over the past two decades is attributable to improvements in neonatal intensive care for very-low-birthweight infants. Yet large and persistent disparities persist in the quality of neonatal intensive care across hospitals. Improving care for infants now served by hospitals with poor outcomes can greatly reduce infant mortality, particularly among minority infants who are more likely to be very low birthweight and cared for by hospitals with poor outcomes. Referral of high-risk births to hospitals with the best outcomes is another promising strategy.

Rogstad KE, Holkar S, Dewdney A. Sexual health needs of the under-16s attending an STI clinic: what are they and are they being addressed? *Int J STD AIDS* 2003; 14(4):266-9.

Abstract: A retrospective analysis was performed on case notes of patients aged less than 16 years who attended a Department of Genito-Urinary Medicine as a new case in 1998. Seventy-four case notes were reviewed. There was a high rate of sexually transmitted infection (STI) (gonorrhoea six [8%], chlamydia 23 [31%], genital warts nine [12%], trichomonas seven [10%]) and low condom (30, 41%) and other contraceptive use (21 females [35%], six males [60%]). Many female attendees were victims of current or previous sexual abuse (eight, 8%) and/or exploitation, and for a further eight (8%) abuse/exploitation was considered possible; little reference was made to this in the notes. Thirty-three (45%) attendees were seen by junior members of staff, and only 49 (60%) were seen by a health adviser (42 females, seven males [60%]). Young attendees have a high STI rate, low contraceptive use and a significant minority are victims of abuse. Genitourinary medicine clinics need to provide a full sexual health service to this vulnerable group and have guidelines in place to assess for sexual abuse. Recommendations on how to achieve this are given.

Rohde DL. Learnability, stochastic input, and connectionist networks: a response to Brian MacWhinney's 'A multiple process solution to the logical problem of language acquisition'. *J Child Lang* 2004; 31(4):954-8; discussion 963-8.

Rolle U, Piotrowska AP, Nemeth L, Puri P. Altered distribution of interstitial cells of Cajal in Hirschsprung disease. *Arch Pathol Lab Med* 2002; 126(8):928-33. Abstract: CONTEXT: Constipation or recurrent intestinal dysmotility problems are common after definitive surgical treatment in Hirschsprung disease (HD). c-Kit-positive interstitial cells of Cajal (ICCs) play a key role in the motility function and development of the gastrointestinal tract. Interstitial cells of Cajal that carry the tyrosine kinase receptor (c-Kit) develop as either myenteric ICCs or muscular ICCs under the influence of the kit ligand, which can be provided by neuronal and nonneuronal cells, for example, smooth muscle cells. OBJECTIVE: To investigate the distribution of myenteric and muscular ICCs in different parts of the colon in HD. METHODS: Resected bowel specimens from 8 patients with rectosigmoid HD were investigated using combined staining with c-Kit enzyme and fluorescence immunohistochemistry and acetylcholinesterase and nicotinamide adenine dinucleotide phosphate (NADPH) histochemistry in whole-mount preparations and conventional frozen sections. RESULTS: In the normal bowel, ICCs formed a dense network surrounding the myenteric plexus and at the innermost part of the circular muscle. Myenteric ICCs were

absent or sparse in the aganglionic bowel and sparse in the transitional zone. The expression of myenteric ICCs in the ganglionic bowel in HD was reduced compared to that in the normal bowel, and they formed only sparse networks. Muscular ICCs were found in the aganglionic bowel, transitional zone, and normoganglionic bowel of HD in a reduced density compared to the normal bowel. CONCLUSION: This study demonstrates altered distribution of ICCs in the entire resected bowel of HD patients. This finding suggests that persistent dysmotility problems after pull-through operation in HD may be due to altered distribution and impaired function of ICCs.

Rosen LN, O'Sullivan CS. Outcomes of custody and visitation petitions when fathers are restrained by protection orders: the case of the New York family courts. *Violence Against Women* 2005; 11(8):1054-75. Abstract: A random sample of custody and visitation petitions filed in New York City Family Courts in 1995 was used to examine outcomes of mothers' Order of Protection (OP) Petitions in relation to parents' custody and visitation petitions. Fathers restrained by OPs were more likely to secure visitation orders (64%) than not. In contrast, 80.8% of fathers' custody petitions were dismissed when they were restrained by OPs. Fathers' custody petitions were most likely to be ordered when mothers' OP petitions were withdrawn. Mothers were most likely to secure custody when their OP petitions were ordered or withdrawn. Courts rarely denied petitions. Those that did not result in court orders were either withdrawn by the petitioner or dismissed by the court (most likely because of failure of the petitioner to appear in court). This pattern has negative implications for battered women who may be vulnerable to pressure or threats from abusive ex-partners.

Rosenberg AD, Abell SC, Mackie JK. An examination of the relationship between child sexual offending and psychopathy. *J Child Sex Abus* 2005; 14(3):49-66. Abstract: The participants in this study were adult males (N = 111) who were accused of various sexual crimes against children 16 years of age or younger, and

who were evaluated at a state forensic facility in a large Midwestern state. This study examined the relationship of Psychopathy Checklist-Revised (PCL-R) scores to type of child sexual offender (same sex extrafamilial, opposite sex extrafamilial, and incest offenders), the presence of violence during the most recent child sexual offense, and criminal versatility. Results indicated that those sexual offenders who employed physical violence against the children they abused were significantly more psychopathic than those who did not. No significant differences were found between types of child sexual offenders or with general criminal versatility.

Rosenberg DA. Munchausen Syndrome by Proxy: medical diagnostic criteria. *Child Abuse Negl* 2003; 27(4):421-30.

Abstract: Medical diagnostic criteria for Munchausen Syndrome by Proxy are presented. The strength of the known facts may vary from case to case, and thus there may be different degrees of diagnostic conviction. Therefore, diagnostic criteria for a definitive diagnosis, and a possible diagnosis of Munchausen Syndrome by Proxy are provided. Because the gathering of evidence in a case may, ultimately, diminish or exclude the diagnosis of Munchausen Syndrome by Proxy, diagnostic criteria for the inconclusive determination and the definitely excluded diagnosis are also enunciated.

Rosenberg MF, Anthony JC. Aggressive behavior and opportunities to purchase drugs. *Drug Alcohol Depend* 2001; 63(3):245-52.

Abstract: Robins, Kellam, and others found robust evidence linking youthful aggression and deviance to later illicit drug use. Some investigators favor the interpretation that drug use is just one manifestation or complication of a more general problem behavior syndrome or conduct disorder. In this work, we test the complementary hypothesis that aggressive youths are more likely to be approached with offers to buy drugs, and found the most aggressive youths were about five times more likely to be offered drugs for purchase. However, this association was much attenuated when levels of delinquency were taken into account. In this respect, delinquent rather than aggressive behavior might be more salient. This study's evidence does not contradict previous problem behavior theories, but rather prompts new ideas about how aggression, delinquency, and drug use might be linked. One testable hypothesis is that youths with both aggression and delinquency are more likely to enter microenvironments where drug dealing is more prevalent. Or, their observable behaviors or physical appearance might function as signs of apparent willingness to try drugs. These results add to our understanding of links between aggression, delinquency, and drug use, and introduce a new line of epidemiological inquiry focused upon drug purchase opportunities.

Rosenblum A, Magura S, Fong C *et al.* Substance use among young adolescents in HIV-affected families: resiliency, peer deviance, and family functioning. *Subst Use Misuse* 2005; 40(5):581-603. Abstract: This study examines the association of risk and protective factors with substance use among 77 early adolescents (11-15 years old) with an HIV-infected parent who were interviewed in 2000-2001 in the South Bronx, a HIV high-prevalence area of New York City. The subjects were 49% female, 53% African American, and 30% Hispanic; mean age was 13 years old. A face-to-face interview was used to administer a battery of instruments representing community, family, peer, and resiliency factors. Forty percent reported ever using tobacco, alcohol or drugs; 71% were aware of their parent's HIV seropositivity. An age-adjusted path analytic model was constructed which showed: 1) family functioning predicted resiliency (a composite measure of psychological adjustment and personal competencies); 2) positive community factors and resiliency predicted less affiliation with deviant peers; and 3) poorer family functioning and affiliation with deviant peers predicted substance use. These results underscore the need for interventions that address social influence factors among vulnerable early adolescents with HIV-positive parents.

Rosenfeld RM. Observation option toolkit for acute otitis media. *Int J Pediatr Otorhinolaryngol* 2001; 58(1):1-8.

Abstract: The observation option for acute otitis media (AOM) refers to deferring antibiotic treatment of selected children for up to 3 days, during which time management is limited to analgesics and symptomatic relief. With appropriate follow-up complications are not increased, and clinical outcomes compare favorably with routine initial antibiotic therapy. Although used commonly in the Netherlands and certain Scandinavian countries, this approach has not gained wide acceptance in Europe and the United States. This article describes an evidence-based toolkit developed by the New York Region Otitis Project for judicious use of the observation option. The toolkit is not intended to endorse the observation option as a preferred method of management, nor is it intended as a rigid practice guideline to supplant clinician judgement. Rather, it presents busy clinicians with the tools needed to implement the observation option in everyday patient care should they so desire.

Rosenfield RL, Bernardo LM. Pediatric implications in

bioterrorism part II: postexposure diagnosis and treatment. *Int J Trauma Nurs* 2001; 7(4):133-6. Abstract: Bioterrorism is an old tactic used in warfare. The use of fatal diseases or man-made poisons to subdue others has not been limited to wartime. Trauma personnel should be aware of commonly used agents, the signs and symptoms of their exposure, and recommended treatment. Children can be victims of terrorists' acts and need special attention because of their unique response to exposure, varying dosages of medications, and lack of active immunity.

Rosenfield S, Lennon MC, White HR. The self and mental health: self-salience and the emergence of internalizing and externalizing problems. *J Health Soc Behav* 2005; 46(4):323-40.

Abstract: How do schemas about self-salience--the importance of the self versus the collective in social relations--affect mental health? We propose that self-salience shapes the likelihood of experiencing internalizing or externalizing problems. Schemas that privilege others over the self increase the risk of internalizing symptoms, including depressive symptoms and anxiety, whereas those that privilege the self over others predispose individuals to externalizing behaviors of antisocial behavior and substance abuse. Furthermore, we propose that these schemas contribute to the gender differences that exist in these problems. We test these predictions with data from adolescents, the stage at which these problems and the gender differences in them arise. Results show that self-salience underlies both internalizing and externalizing problems. In addition, schemas about self-salience help explain the gender differences found in mental health problems.

Rosenthal J, Rodewald L, McCauley M *et al.* Immunization coverage levels among 19- to 35-month-old children in 4 diverse, medically underserved areas of the United States. *Pediatrics* 2004; 113(4):e296-302. Abstract: **BACKGROUND:** The National Immunization Survey demonstrates that national immunization coverage in 2002 remained near the all-time highs achieved in 2000. However, that survey cannot detect whether coverage is uniformly high within relatively small areas or populations. The measles resurgence in the early 1990s revealed that coverage was low in some areas, particularly among inner-city children from racial and ethnic minority groups. Today, identifying areas with low childhood-vaccination coverage remains important, particularly if these areas are at risk for the introduction of disease. In 1995, the Centers for Disease Control and Prevention launched a congressionally mandated demonstrated project now called the Childhood Immunization Demonstration project of Community Health Networks. This mandate specified an assessment to determine whether a network of primary care providers affiliated with university teaching hospitals could assume a public health responsibility for raising

immunization levels among preschoolers in medically underserved communities. Communities with federally designated health professional shortage areas were invited to submit proposals, and 4 were selected: Detroit, MI, New York, NY, San Diego, CA, and rural Colorado. **OBJECTIVES:** To measure immunization coverage among preschool children in the 4 selected medically underserved areas and determine predictors of coverage levels. **DESIGN AND SETTING:** Surveys in the 4 areas were based on stratified cluster probability sample designs in which clusters of dwelling units were selected and all households in selected clusters were screened for the presence of children aged 12 to 35 months. Immunization histories were obtained from parents and providers for these children. For each age-eligible child, the information collected on utilization of immunization health services included a listing of all clinics or offices ever used for the child's well-child care and/or for obtaining immunizations. Information was also collected on whether the child currently had health insurance (public and/or private) and whether the child had a medical home. A child was classified as having a medical home if the survey respondent reported a source of well care that was the same as the source of sick care and that this place was not an emergency department. **PARTICIPANTS:** Children 12 to 35 months of age in Detroit, New York, San Diego, and rural Colorado. **OUTCOME MEASURE:** Community-wide up-to-date (UTD) immunization coverage levels at 19 to 35 months of age, defined as receipt of 4 doses of diphtheria and tetanus toxoids and pertussis vaccine, 3 doses of poliovirus vaccine, 1 dose of measles, mumps, and rubella vaccine, 3 doses of Haemophilus influenzae type B vaccine, and 3 doses of hepatitis B vaccine (the 4:3:1:3:3 series). **ANALYSIS:** We examined the association between coverage level and independent variables and performed chi<sup>2</sup> and t tests to determine whether differences observed within and between groups and sites were significant. **RESULTS:** The overall response rate for eligible children ranged from 79.4% to 88.1%. Coverage levels for most individual vaccines were >90% in all sites except Detroit. Coverage for the 4:3:1:3:3 series was significantly higher for children in New York (84%) and San Diego (86%) than for children in Detroit (66%) and rural Colorado (75%). Demographic risk factors related to UTD immunization status varied by site. Although differences in coverage levels by ethnicity varied by site, differences were not significant. In Colorado and New York, coverage was slightly lower among Hispanic than white children (71% vs 76% and 83% vs 91%, respectively). In San Diego, coverage was lower among whites, compared with Hispanics (76% vs 85%). Coverage was also lower for African American than white children only in New York (75% vs 91%). However, in San Diego and Colorado, children receiving their vaccinations from private providers had lower coverage levels than children receiving their vaccinations from other

providers (78% vs 91% and 71% vs 57%, respectively). Ictively). In all 4 sites, children for whom respondents reported having an immunization card at the time of the interview were more likely to have higher series coverage levels than children for whom a parent-held card was not available. Also, children who were UTD at 3 months of age had significantly higher vaccination-series coverage levels than children who were not UTD at 3 months of age. In addition, the vaccination coverage was lower for children in Detroit whose parents reported problems accessing the health care system because lack of transportation (46%), compared with those who did not report such problems (65%); however, this difference did not reach significance ( $\chi^2 = 6.0$ ). In Colorado, the small proportion of children in families without a phone had a lower vaccination coverage level (58%) than those in households with a phone (75%) ( $\chi^2 = 6.3$ ). In all sites, children who were UTD at 3 months of age and had a parent-held vaccination card were more likely to be UTD at 19 to 35 months of age. CONCLUSIONS: Preschoolers in these medically underserved areas were not at uniform risk for underimmunization. Because they were designated as health professional shortage areas, the 4 sites in this study were expected to have low immunization-coverage rates. However, this was not the case. In fact, coverage in 3 of the 4 areas was quite high compared with US national figures (73%); only Detroit had a much lower UTD rate (66%). Efforts are needed to improve methods to identify areas with low immunization coverage so that resources can be directed to places where interventions are needed. Our results reveal that an area's need for childhood immunization interventions is not well predicted by a low number of providers per capita. Other criteria must be developed to predict areas or populations with low immunization coverage. Understanding more about the characteristics of children/provider pairs for children who are UTD at 3 months and more about the role of parental hand-held cards, along with finding strategies to improve immunization delivery by providers in Vaccines for Children Program facilities, suggest potentially productive avenues for increasing and sustaining high coverage levels.

Ross DA, Hinman AR, Saarlal KN, Lloyd-Puryear MA, Downs SJ. The near-term future for child health information systems. *J Public Health Manag Pract* 2004; Suppl:S99-104.  
 Abstract: The developmental process in children offers an opportunity to influence their health and well-being as adults. The information infrastructure of the future needs to support the multiple partners responsible for providing elements of the health protection and health care of children. In this partnership, public health plays simultaneously a supportive role and a leadership role. Five tasks need to guide near-term information systems thinking with respect to establishing a basis for building electronic linkages among various child health

programs. First, the nation's vital records system must be reengineered to ensure that this key information asset can be integrated into other child health information systems. Second, through an appropriate governance structure, the key stakeholders in child health should endorse standards and requirements that define a longitudinal health record for children. Third, public health agencies should develop a thorough business case/value proposition that drives mutually developed and mutually endorsed requirements for the integration of presently fragmented systems. Fourth, public health should take the lead in ensuring that parents have convenient access to information that can support the coordination of their child's care and development. And fifth, provider groups and public health agencies should join research networks to study how information supports positive changes to children's health.

Ross LF. Predictive genetic testing for conditions that present in childhood. *Kennedy Inst Ethics J* 2002; 12(3):225-44.

Notes: GENERAL NOTE: KIE: 58 refs.  
 GENERAL NOTE: KIE: KIE Bib: genetic screening; mass screening

Abstract: There is a general consensus in the medical and medical ethics communities against predictive genetic testing of children for late onset conditions, but minimal consideration is given to predictive testing of asymptomatic children for disorders that present later in childhood when presymptomatic treatment cannot influence the course of the disease. In this paper, I examine the question of whether it is ethical to perform predictive testing and screening of newborns and young children for conditions that present later in childhood. I consider the risks and benefits of (1) predictive testing of children from high-risk families; (2) predictive population screening for conditions that are untreatable; and (3) predictive population screening for conditions in which the efficacy of presymptomatic treatment is equivocal. I conclude in favor of parental discretion for predictive genetic testing, but against state-sponsored predictive screening for conditions that do not fulfill public health screening criteria.

Ross LT, Hill EM. Comparing alcoholic and nonalcoholic parents on the family unpredictability scale. *Psychol Rep* 2004; 94(3 Pt 2):1385-91.

Abstract: Research findings and clinical observations suggest that families with an alcoholic parent are more unpredictable. Alcoholic parents ( $n=25$ , 68% men, 68% Euro-American, M age=38.6 yr.) and community parents ( $n=27$ , 52% men, 70% Euro-American, M age=38.8 yr.) completed the self-report Family Unpredictability Scale of Ross and Hill. Alcoholic parents reported significantly higher (less predictability) scores on the subscales of Nurture, Finances, and Discipline, as well as on the Total Family Unpredictability Scale ( $p < .01$ ). This appears to be the first study on family unpredictability and

parental alcoholism in which parental reports of multiple dimensions of unpredictability are used. We provide suggestions for research and clinical uses of the scale, especially pertaining to families with an alcoholic parent.

Roth D, Boyle E, Beer D, Malik A, deBruyn J. Depressing research. *Lancet* 2004; 363(9426):2087. Notes: GENERAL NOTE: KIE: 4 refs. GENERAL NOTE: KIE: KIE Bib: biomedical research; fraud and misconduct Abstract: Suppression of the publication of negative trials of serotonin-selective reuptake inhibitors (SSRI) in children (Apr 24, p 1335) is more than just a matter of "confusion, manipulation, and institutional failure". It is a crime. To blandly illustrate its severity, we can analogise the situation as follows: would you be concerned if a colleague prescribed penicillin to a child who had an uncomplicated upper respiratory tract infection of viral aetiology? Would you be more concerned if you heard that this child had a serious anaphylactic reaction to the penicillin at home? And how much more concerned would you be if you found out that the prescribing doctor was previously aware of the child's severe penicillin allergy? The latter scenario could be deemed malpractice. How, then, is it acceptable for pharmaceutical companies to suppress publication of SSRI studies that showed a lack of efficacy and an increased risk of serious adverse events in the children and adolescents in experimental trial groups (other than for fluoxetine)? Intentional concealment of these data, an accusation for which there is already public evidence, must be considered a form of corporate violence.

Roth-Kleiner M, Berger TM, Tarek MR, Burri PH, Schittny JC. Neonatal dexamethasone induces premature microvascular maturation of the alveolar capillary network. *Dev Dyn* 2005; 233(4):1261-71. Abstract: Postnatal glucocorticoid treatment of preterm infants was mimicked by treating newborn rats with dexamethasone (0.1-0.01 microg/g, days 1-4). This regimen has been shown to cause delayed alveolarization. Knowing that microvascular maturation (transformation of double- to single-layered capillary networks in alveolar septa) and septal thinning prevent further alveolarization, we measured septal maturation on electron photomicrographs in treated and control animals. In treated rats and before day 10, we observed a premature nonreversing microvascular maturation and a transient septal thinning, which both appeared focally. In vascular casts of both groups, we observed contacts between the two capillary layers of immature alveolar septa, which were predictive for capillary fusions. Studying serial electron microscopic sections of human lungs, we were able to confirm the postulated fusion process for the first time. We conclude that alveolar microvascular maturation indeed occurs by capillary fusion and that the dexamethasone-induced impairment of alveolarization

is associated with focal premature capillary fusion.

Roth TL, Sullivan RM. Memory of early maltreatment: neonatal behavioral and neural correlates of maternal maltreatment within the context of classical conditioning. *Biol Psychiatry* 2005; 57(8):823-31. Abstract: BACKGROUND: While children form an attachment to their abusive caregiver, they are susceptible to mental illness and brain abnormalities. To understand this important clinical issue, we have developed a rat animal model of abusive attachment where odor paired with shock paradoxically produces an odor preference. Here, we extend this model to a seminaturalistic paradigm using a stressed, "abusive" mother during an odor presentation and assess the underlying learning neural circuit. METHODS: We used a classical conditioning paradigm pairing a novel odor with a stressed mother that predominantly abused pups to assess olfactory learning in a seminaturalistic environment. Additionally, we used Fos protein immunohistochemistry to assess brain areas involved in learning this pain-induced odor preference within a more controlled maltreatment environment (odor-shock conditioning). RESULTS: Odor-maternal maltreatment pairings within a seminatural setting and odor-shock pairings both resulted in paradoxical odor preferences. Learning-induced gene expression was altered in the olfactory bulb and anterior piriform cortex (part of olfactory cortex) but not the amygdala. CONCLUSIONS: Infants appear to use a unique brain circuit that optimizes learned odor preferences necessary for attachment. A fuller understanding of infant brain function may provide insight into why early maltreatment affects psychiatric well-being.

Rothenberger A, Danckaerts M, Dopfner M, Sergeant J, Steinhausen HC. EINAQ -- a European educational initiative on Attention-Deficit Hyperactivity Disorder and associated problems. *Eur Child Adolesc Psychiatry* 2004; 13 Suppl 1:I31-5. Abstract: BACKGROUND: Continuing Medical Education (CME) plays an important role in quality management, especially as quality assurance, for the improvement of healthcare in child and adolescent psychiatry. This requires responsibility regarding quality standards of clinical practice throughout Europe as outlined by the European Union of Medical Specialists (UEMS). OBJECTIVE: Therefore, steps should be undertaken to improve specialists' medical care and harmonize it in Europe. Attention-Deficit Hyperactivity Disorder (ADHD) with its many co-existing developmental disorders/problems is the central healthcare problem in child and adolescent psychiatry with high impact on society. Therefore, it was chosen as the target. METHOD: A European Interdisciplinary Network for ADHD Quality Assurance (EINAQ) was founded, didactic material was developed and a faculty of experts from several European countries established to offer all over Europe harmonized courses on ADHD and associated

problems. RESULTS: Pilot courses were given in Germany in 2003/2004 and were highly appreciated by the participants. Further courses in Germany and other European countries will take place in 2004. CONCLUSION: EINAQ seems to be on the right track to be part of CME and specialized networks for healthcare in ADHD to improve the provision for mental health problems in children and adolescents in Europe. Cooperative projects with official European bodies like the UEMS -- Section on Child and Adolescent Psychiatry/Psychotherapy and the European Society of Child and Adolescent Psychiatry could strengthen the impact of EINAQ.

Rotheram-Borus MJ, Lee M, Leonard N *et al.* Four-year behavioral outcomes of an intervention for parents living with HIV and their adolescent children. *AIDS* 2003; 17(8):1217-25.  
Abstract: OBJECTIVE: The adjustment of parents living with HIV (PLH) and their adolescent children was examined over 4 years in response to an intervention. Outcomes at 2 years had been previously published. METHODS: A randomized controlled trial was conducted, with a representative sample from New York City. RESULTS: In the intervention condition, fewer adolescents became teenage parents, and conduct problems tended to be lower over 4 years than in the standard care condition. Fewer parents were drug dependent and tended to relapse into substance use or use passive coping styles compared with the standard care condition over 4 years. The time-trend analysis showed that the significant reductions in problem behaviors and emotional distress previously observed over 15-24 months in the intervention condition, then eroded over time and were non-significant at 48 months. CONCLUSIONS: Ongoing support and skills are needed to maintain intervention effects over longer periods.

Rotheram-Borus MJ, Lee MB, Murphy DA *et al.* Efficacy of a preventive intervention for youths living with HIV. *Am J Public Health* 2001; 91(3):400-5.  
Notes: CORPORATE NAME: Teens Linked to Care Consortium  
Abstract: OBJECTIVES: HIV transmission behaviors and health practices of HIV-infected youths were examined over a period of 15 months after they received a preventive intervention. METHODS: HIV-infected youths aged 13 to 24 years (n = 310; 27% African American, 37% Latino) were assigned by small cohort to (1) a 2-module ("Stay Healthy" and "Act Safe") intervention totaling 23 sessions or (2) a control condition. Among those in the intervention condition, 73% attended at least 1 session. RESULTS: Subsequent to the "Stay Healthy" module, number of positive lifestyle changes and active coping styles increased more often among females who attended the intervention condition than among those in the control condition. Social support coping also increased significantly among males and females attending the

intervention condition compared with those attending the control condition. Following the "Act Safe" module, youths who attended the intervention condition reported 82% fewer unprotected sexual acts, 45% fewer sexual partners, 50% fewer HIV-negative sexual partners, and 31% less substance use, on a weighted index, than those in the control condition. CONCLUSIONS: Prevention programs can effectively reduce risk acts among HIV-infected youths. Alternative formats need to be identified for delivering interventions (e.g., telephone groups, individual sessions).

Rousseau C, Machouf A. A preventive pilot project addressing multiethnic tensions in the wake of the Iraq war. *Am J Orthopsychiatry* 2005; 75(4):466-74.  
Abstract: This article describes a school-based preventive pilot project for recent immigrant children, designed to decrease anxiety and intergroup tensions associated with the Iraq war. Results suggest that clinicians should address the multiplicity of meanings associated with international events when planning a prevention program in multiethnic schools to help children to cope with the increasingly common gap between the ways traumatic events covered by the media are understood at home and at school.

Rovers MM, Straatman H, Ingels K, van der Wilt GJ, van den Broek P, Zielhuis GA. Generalizability of trial results based on randomized versus nonrandomized allocation of OME infants to ventilation tubes or watchful waiting. *J Clin Epidemiol* 2001; 54(8):789-94.  
Abstract: The objective was to study the generalizability of trial results by comparing randomized patients to eligible but nonrandomized patients who received the same management. Implementation of trial results is only justifiable when the results can be generalized to the total domain population. The design was a multicentre randomized controlled trial on the effect of early screening and treatment with ventilation tubes on infants with otitis media with effusion. Randomized (n = 187) and nonrandomized eligible patients (n = 133) were followed up. The study population comprised children who were detected by auditory screening at the age of 9-12 months and who were subsequently diagnosed with persistent bilateral otitis media with effusion for 4-6 months. A significant difference was found in the distribution of some prognostic factors: more randomized children had older siblings, did not attend day care and had mothers with a lower educational level than the nonrandomized children. These factors, however, did not modify the outcome. No differences were found in mean hearing levels between the randomized and nonrandomized children: in both the randomized and nonrandomized children ventilation tubes improved the hearing level, especially after 6 months. However, in the long term (12 months), the hearing levels were equal again. The results of the

randomized and nonrandomized patients were comparable. The results of this trial appear to be generalizable to the total domain population. The procedure of following up both randomized and nonrandomized patients is recommended when there is concern about selective participation and reduced generalizability.

Rowe J. A room of their own: the social landscape of infant sleep. *Nurs Inq* 2003; 10(3):184-92. Abstract: This paper draws on findings of a study in which new and experienced mothers' caregiving practices were investigated, in order to examine social perspectives of infant sleep. Health professionals who work to support early parenting and promote child health and well-being provide guidance to their clients concerning infant sleep cares. Currently, advice is predominantly informed by understandings and strategies derived from Sudden Infant Death Syndrome (SIDS) risk reduction campaigns and behavioural training models. The social context of caregiving is a significant if somewhat neglected perspective. The analysis presented in this paper suggests that in sleep arrangements, a complex social locale is revealed, an elaboration of carers' values and understandings about infants as developing persons, juxtaposed with their own desires and needs. Tensions between child-centred nurturing and adult-focused concerns are expressed and reconciled in caregiving. These understandings may assist health professionals to develop proactive and responsive practices in the area of early childrearing support.

Rowe R, Maughan B, Worthman CM, Costello EJ, Angold A. Testosterone, antisocial behavior, and social dominance in boys: pubertal development and biosocial interaction. *Biol Psychiatry* 2004; 55(5):546-52.

Abstract: **BACKGROUND:** Studies linking testosterone and antisocial behavior in humans have produced mixed results. Adolescence offers a promising period to study this relationship; circulating testosterone increases dramatically in boys during puberty, and antisocial behavior increases during the same period. **METHODS:** Our analyses were based on boys aged 9-15 years who were interviewed during the first three waves of the Great Smoky Mountains Study. Measures included interview assessment of DSM-IV conduct disorder (CD) symptoms and diagnosis, blood spot measurement of testosterone, Tanner staging of pubertal development, and assessment of leadership behaviors and peer deviance. **RESULTS:** The adolescent rise in CD was primarily attributable to an increase in nonphysically aggressive behaviors. Increasing levels of circulating testosterone and association with deviant peers contributed to these age trends. There was no evidence that physical aggression was related to high testosterone. Evidence of biosocial interactions was identified; testosterone was related to nonaggressive CD symptoms in boys with deviant

peers and to leadership in boys with nondeviant peers. **CONCLUSIONS:** The results are consistent with the hypothesis that testosterone relates to social dominance, with the assumption that behaviors associated with dominance differ according to social context.

Rowling AJ, Kvalsvig AJ, Sharples PM, Foot AB, Unsworth DJ. Pneumocystis carinii, cytomegalovirus, and severe transient immunodeficiency. *J Clin Pathol* 2003; 56(9):718-9.

Abstract: Pneumocystis carinii infection is rare in infants, and raises strong concerns of immune deficiency. This report describes the unusual case of a male infant with concurrent chest infections caused by P carinii and cytomegalovirus. Investigation was complicated by the strong suspicion of non-accidental injury, including subdural haematomas. The case illustrates how to investigate for possible immunodeficiency. Low immune function tests at presentation slowly improved and have remained normal on longterm follow up. Possible explanations for the transient severe clinical immunodeficiency in this case are discussed.

Roy A. Childhood trauma and impulsivity. Possible relevance to suicidal behavior. *Arch Suicide Res* 2005; 9(2):147-51.

Abstract: Social factors are thought to contribute to impulsivity. As childhood traumas predispose to suicidal behavior it was decided to examine whether they may be a determinant of impulsivity, a personality dimension often associated with suicidal behavior. Thus 268 abstinent drug dependent patients completed both the Childhood Trauma Questionnaire (CTQ) and the Barratt Impulsivity Scale (BIS). The results showed that there were significant relationships, albeit small, between CTQ scores and BIS impulsivity scores. These results suggest that childhood trauma may be one determinant of impulsivity as an adult.

Roy A. Relationship of childhood trauma to age of first suicide attempt and number of attempts in substance dependent patients. *Acta Psychiatr Scand* 2004; 109(2):121-5.

Abstract: **OBJECTIVE:** To examine whether childhood trauma effect the age of first attempting suicide and the number of attempts. **METHOD:** One thousand twelve hundred and eighty substance dependent patients were interviewed about whether or not they had ever attempted suicide, the age of first attempt and the number of attempts. Patients completed the Childhood Trauma Questionnaire - 34 item version. **RESULTS:** Five hundred and thirty-eight patients (42%) had attempted suicide. Significantly more of the patients who had attempted suicide were female. Patients who had made three or more attempts had significantly higher childhood trauma scores than patients who had made two attempts, who had higher scores than

patients who had made one attempt, who had higher scores than patients who had never attempted. Patients who first attempted suicide before the age of 20 years had significantly higher childhood trauma scores than patients who first attempted after 20 years of age. CONCLUSION: Childhood trauma may be a determinant of the age of onset of suicidal behavior and of the number of suicide attempts.

Roy A, Janal M. Family history of suicide, female sex, and childhood trauma: separate or interacting risk factors for attempts at suicide? *Acta Psychiatr Scand* 2005; 112(5):367-71.

Abstract: OBJECTIVE: Female sex, childhood trauma, and a family history of suicidal behavior are three well established risk factors for attempting suicide. However, interactions between these three factors in attempting suicide have been little studied. METHOD: One thousand eight hundred and eighty-nine abstinent substance dependent patients were interviewed about their lifetime and family history of suicidal behavior and completed the Childhood Trauma Questionnaire (CTQ). Gender, family history of suicidal behavior, and CTQ scores--and their interaction--were examined in relation to suicidal behavior. RESULTS: Each of the three risk factors was associated with at least a doubling of the risk for an attempt at suicide. There were no significant interactions in relation to the risk of making an attempt. However, female sex and higher levels of childhood trauma each discriminated patients at risk for both a younger age of first attempting suicide and for making more attempts. CONCLUSION: Female sex, childhood trauma, and a family history of suicidal behavior are each independent, and non-interacting, risk factors for attempting suicide. Additionally, female sex and high childhood trauma are independent risk factors for both an early onset of first attempting suicide and for making more attempts.

Rube DM, Kibel RN. The Jewish child, adolescent, and family. *Child Adolesc Psychiatr Clin N Am* 2004; 13(1):137-47.

Abstract: This brief review addresses the history, beliefs, and practices of Jewish families that have implications for clinical management of the problems and disorders of children and adolescents. It focuses primarily on the problems of the Orthodox family due, in part, to the limitations of space. There remains, however, little doubt that the clinician must be aware of the impact that Jewish heritage may have on the clinical issues at hand. This impact is significant whether the worldview of the family is characterized by strict Orthodoxy or is primarily that of an ethnic identification with less concern for belief and practice.

Rueda MR, Posner MI, Rothbart MK, Davis-Stober CP. Development of the time course for processing conflict: an event-related potentials study with 4 year

olds and adults. *BMC Neurosci* 2004; 5(1):39. Abstract: BACKGROUND: Tasks involving conflict are widely used to study executive attention. In the flanker task, a target stimulus is surrounded by distracting information that can be congruent or incongruent with the correct response. Developmental differences in the time course of brain activations involved in conflict processing were examined for 22 four year old children and 18 adults. Subjects performed a child-friendly flanker task while their brain activity was registered using a high-density electroencephalography system. RESULTS: General differences were found in the amplitude and time course of event-related potentials (ERPs) between children and adults that are consistent with their differences in reaction time. In addition, the congruency of flankers affected both the amplitude and latency of some of the ERP components. These effects were delayed and sustained for longer periods of time in the children compared to the adults. CONCLUSIONS: These differences constitute neural correlates of children's greater difficulty in monitoring and resolving conflict in this and similar tasks.

Rueda MR, Rothbart MK, McCandliss BD, Saccomanno L, Posner MI. Training, maturation, and genetic influences on the development of executive attention. *Proc Natl Acad Sci U S A* 2005; 102(41):14931-6. Abstract: A neural network underlying attentional control involves the anterior cingulate in addition to lateral prefrontal areas. An important development of this network occurs between 3 and 7 years of age. We have examined the efficiency of attentional networks across age and after 5 days of attention training (experimental group) compared with different types of no training (control groups) in 4-year-old and 6-year-old children. Strong improvement in executive attention and intelligence was found from ages 4 to 6 years. Both 4- and 6-year-olds showed more mature performance after the training than did the control groups. This finding applies to behavioral scores of the executive attention network as measured by the attention network test, event-related potentials recorded from the scalp during attention network test performance, and intelligence test scores. We also documented the role of the temperamental factor of effortful control and the DAT1 gene in individual differences in attention. Overall, our data suggest that the executive attention network appears to develop under strong genetic control, but that it is subject to educational interventions during development.

Ruess L, Uyehara CF, Shiels KC *et al*. Digitizing pediatric chest radiographs: comparison of low-cost, commercial off-the-shelf technologies. *Pediatr Radiol* 2001; 31(12):841-7.

Abstract: OBJECTIVE: To compare low-cost, off-the-shelf technology for digitizing pediatric chest radiographs. MATERIALS AND METHODS: Forty pediatric chest radiographs (hard copy), each with a

single abnormality, were digitized using a commercial film digitizer and two low-cost METHODS: a digital camera and a flatbed scanner. A stratified, randomized, block design was used where 20 readers evaluated 40 different images to determine the ability to accurately detect the abnormality. Readers then rated all 160 images (40 images x 4 methods) for conspicuity of the abnormality and overall image quality. RESULTS: Abnormalities were correctly identified on 82.3 % of hard copy images, 82.9 % of flatbed scanner images, 74.3 % of film digitizer images, and 69.7 % of digital camera images ( $p < 0.05$ ) when compared to hard copy or flatbed scanner images. Lesion conspicuity was rated higher on hard copy ( $p < 0.05$ ) than all digitized images. Conspicuity ratings were similar for flatbed scanner and film digitizer images, but lower in digital camera images ( $p < 0.05$ ). For overall image quality, all were rated significantly different from each other ( $p < 0.05$ ), with hard copy > flatbed scanner > film digitizer > digital camera images. CONCLUSION: A low-cost flatbed scanner yielded digital pediatric chest images which were significantly superior to digital camera images. While flatbed scanner images were interpreted with the equivalent diagnostic accuracy of hard copy images, they were rated lower for image quality and lesion conspicuity.

Ruiz RJ, Brown CE, Peters MT, Johnston AB. Specialized care for twin gestations: improving newborn outcomes and reducing costs. *J Obstet Gynecol Neonatal Nurs* 2001; 30(1):52-60. Abstract: OBJECTIVE: To compare newborn outcomes and costs of hospital stays for twins born to mothers receiving care in a specialized twin clinic with a research-based care protocol and one consistent caregiver versus twins whose mothers received standard prenatal care. DESIGN AND SETTING: A retrospective, historical cohort study conducted in a high-risk obstetric clinic in central Texas. PATIENTS: Thirty women pregnant with twins received specialized care. The comparison group consisted of 41 women pregnant with twins who received standard care. INTERVENTIONS: An advanced practice nurse provided prenatal care, which included weekly clinic visits, home visits, and 24-hour availability for phone support. OUTCOME MEASURES: Gestational age at birth, birth weight, length of stay in the neonatal intensive-care unit (NICU), and hospital charges for the newborns. RESULTS: No newborns of less than 30 weeks gestation were born to women in the specialized care group, the mean birth weight was 249 g (SD +/- 77) higher, days in the NICU were reduced from a mean of 17 to 7, and hospital charges were \$30,000 less per infant. CONCLUSIONS: Newborn outcomes were improved and length of stay and hospital charges were significantly reduced for newborns whose mothers had received care in the specialized twin clinic.

Ruperto N, Martini A. International research networks in  
817

pediatric rheumatology: the PRINTO perspective. *Curr Opin Rheumatol* 2004; 16(5):566-70. Abstract: PURPOSE OF REVIEW: The purpose of this review is to highlight the problems and possible solutions for the conduct of international collaborative research for pediatric rheumatic diseases. RECENT FINDINGS: Pediatric rheumatic diseases are rare conditions associated with important sequelae on the quality of life and long-term outcome. The research aimed at studying new therapeutic approaches is difficult because of logistic, methodological, and ethical problems. To face these problems, two international networks have been founded: the Pediatric Rheumatology Collaborative Study Group (or PRCSG) and the Paediatric Rheumatology international Trials Organization (or PRINTO). The two networks have the goal to promote, facilitate, and conduct high-quality research into pediatric rheumatic diseases. In particular they have been able to standardize the evaluation of response to therapy in juvenile idiopathic arthritis, juvenile systemic lupus erythematosus, and juvenile dermatomyositis; to draft clinical remission criteria in juvenile idiopathic arthritis; and to provide cross-cultural adapted and validated quality-of-life instruments like the Childhood Health Assessment Questionnaire and the Child Health Questionnaire in 32 different languages. SUMMARY: The creation of large international trial networks such as PRINTO and PRCSG, the definition of internationally recognized and standardized outcome measures and definitions of improvement, the validation of quality-of-life instruments, and the adoption of adequate legislative measures (pediatric rule) have created the basic premises for the best future assessment of pediatric rheumatic diseases. This progress now affords children with pediatric rheumatic diseases the same opportunities as adults to be treated with drugs whose safety and efficacy have been assessed through legitimate scientifically valid investigations.

Rusch MD, Gould LJ, Dzwierzynski WW, Larson DL. Psychological impact of traumatic injuries: what the surgeon can do. *Plast Reconstr Surg* 2002; 109(1):18-24. Abstract: In their treatment of accident and assault victims, plastic surgeons have unique opportunities to identify and refer patients with posttraumatic stress symptoms. This article describes brief assessments that surgeons or their clinic staff can use to evaluate traumatically injured adults and children for trauma-related psychological symptoms. An immediate postinjury evaluation (within 10 days of the trauma) consists of 11 questions to determine the presence of the following risk factors for posttrauma maladjustment: panic during or immediately after the trauma, reexperiencing symptoms, avoidance, sleep disturbance, injury from an assault, previous trauma and psychiatric history, and blaming someone else for the injury. The seven follow-up interview questions

assess reexperiencing symptoms, avoidance, trauma-related phobias, depression, irritability, and increased substance use, all of which, if present, suggest psychological impairment. Questions recommended for the evaluation of younger children assess changes in play and recreational activity, sleep disturbance, night terror, aggression, irritability, avoidance, emergence of new fears, and loss of recently acquired developmental skills. The assessments require less than 2 minutes and are easily integrated into the hospital or clinic examinations of these patients.

Rushton CH. A framework for integrated pediatric palliative care: being with dying. *J Pediatr Nurs* 2005; 20(5):311-25.

Abstract: Recent studies highlight the need for an integrated model for palliative and end-of-life pediatric care. About 55,000 children die each year in the United States and, on any given day, about 8,600 children could benefit from care that acknowledges their limited life expectancy and severity of illness. Two case studies of children illustrate different approaches—one that aggressively applies all possible technologies to maximize chances of survival and another that focuses on the patient's overall quality of life and on healing rather than curing. The cases highlight characteristics of an integrated model of palliative care to address clinical, moral, and ethical uncertainties. This model integrates being with doing, provides for developing attunement and presence as capacities for being with children and their parents, and addresses challenges in the healthcare environment. Strategies for integrating palliative care into pediatric practice include listening, fostering respect for the child and parents across the organization, nurturing collaborative connections, managing uncertainty, tolerating ambiguity, making peace with conflict, and committing to self-care. Every pediatric nurse can play a role in making the vision of palliative care a reality integrated into the fabric of pediatric practice.

Russell-Johnson H. Child protection: defining 'harm'. *Paediatr Nurs* 2003; 15(9):42-3.

Russell M, Lazenbatt A, Freeman R, Marcenes W. Child physical abuse: health professionals' perceptions, diagnosis and responses. *Br J Community Nurs* 2004; 9(8):332-8.

Abstract: The objectives of this cross-sectional survey were to assess primary health professionals' perceptions of and ability to recognize child physical abuse in their practice. A random sample was taken of 979 nurses, doctors, and dentists working in primary care in Northern Ireland. The response rate was 44%, and the results showed that 59% of respondents had

seen a suspicious case of child physical abuse, of which 47% (n = 201) had reported it. Ability and willingness to recognize and report abuse varied across the three professions. The findings suggest a professional reluctance to engage in recognizing and reporting abuse. The barriers could be reduced by providing multi-professional and inter-agency training, support for the primary health professionals in practice, as well as higher education programmes at undergraduate and postgraduate levels for nursing, dentistry and medicine.

Russoniello CV, Skalko TK, O'Brien K, McGhee SA, Bingham-Alexander D, Beatley J. Childhood posttraumatic stress disorder and efforts to cope after Hurricane Floyd. *Behav Med* 2002; 28(2):61-71. Abstract: The authors report on the level of posttraumatic stress disorder (PTSD) experienced by fourth-grade children 6 months after Hurricane Floyd and describe the children's efforts to cope with their stress. All of the children they studied were directly affected by the hurricane, secondary to the destruction of their school by floodwaters. The homes of 37% of these children were also flooded. Ninety-five percent of the children experienced at least mild symptoms of PTSD, and 71% had symptoms that were moderate to very severe. Children who reported that their homes were flooded were 3 times more likely to report symptoms than those whose homes were not flooded, and the girls were twice as likely as the boys to report symptoms. The high PTSD prevalence rates are comparable to findings from other studies involving violence in which 94% of the victims reported experiencing symptoms. For further analyses, the authors used symptom clusters of hyperarousal, numbing/avoidance, and reexperiencing symptoms.

Rutherford MS, Roux GM. Health beliefs and practices in rural El Salvador: an ethnographic study. *J Cult Divers* 2002; 9(1):3-11.

Abstract: OBJECTIVE: To investigate the health practices and lifeways of rural villagers in a remote area of El Salvador who had been displaced by the recent civil war. The purpose of the study was to explore their view on health and experiences of loss during the war. DESIGN: Ethnography (Spradley, 1980, 1999; Agar, 1996). METHOD: The participants included any resident of three rural Salvadoran villages who were 18 years of age and over. Participants included nine families, with a total of twelve participants. Data collection included participant observation, audiotaped interviews, demographic information, and field notes. One of the Spanish-speaking key informants acted as the interpreter. The content of all data was analyzed for recurrent themes. FINDINGS: All nine families were displaced to refugee camps in Honduras during the civil war. Two cultural themes that emerged from the data were: 1) War: "We lost everything; we had to leave running," and 2) Health: "It's in God's hands." CONCLUSIONS:

It is a challenge to encourage culture-specific care that acknowledges Salvadoran herbal remedies, strength of spirit, and a belief that a Supreme Being controls their lives. The health practices of the participants were shaped by their experiences of suffering from loss of family members during the war, displacement from their homes, and lack of potable water and environmental sanitation. IMPLICATIONS: To make a positive impact and effect change on health services in these rural areas, efforts should be directed toward democratic and community-based social and economic development within the context of the cultural system. Recent earthquakes (2001) have intensified the need for improvement in environmental factors including potable water.

Ruths S, Steiner H. Psychopharmacologic treatment of aggression in children and adolescents. *Pediatr Ann* 2004; 33(5):318-27.

Abstract: Knowledge regarding psychopharmacology is increasingly based on clinical trials and rational algorithms. Medications are increasingly regarded as useful adjuncts in the treatment of maladaptive aggression, whether it appears as a target symptom or as a complication of a whole range of psychopathology. Properly integrated into a treatment package that uses psychotherapies and environmental manipulation, medications can provide relief from one of the most destructive forms of psychopathology. Still, more controlled clinical trials are needed, especially those comparing active interventions and those testing the synergistic and antagonistic effects of different treatment modalities.

Ryan G. Undefined use of the terms "child sexual touching" and "child sexual contact". *Child Abuse Negl* 2002; 26(1):3-4; author reply 5-10.

Ryan RM. The developmental line of autonomy in the etiology, dynamics, and treatment of borderline personality disorders. *Dev Psychopathol* 2005; 17(4):987-1006.

Abstract: Borderline personality disorder (BPD) is considered as a disorder of autonomy, and is related to both predisposing vulnerabilities and social relationships that fail to support basic psychological needs. Autonomy, which is defined within the self-determination theory as the capacity for self-endorsed action based on integrative, reflective awareness, is discussed as a developmental line that is dependent on specific supports from caregivers. Unresponsiveness, invalidation, or abuse by caregivers is argued to impair the capacity for autonomy and to catalyze an array of processes, both biological and psychological, which impact subsequent development and, in vulnerable individuals, can lead to BPD. Aspects of treatment, including the emphases on validation and acceptance of the patient's experience, and the cultivation of more reflective or mindful regulation of behavior, can be

deduced, from this analysis of autonomy disturbance, and these in turn have appeared as the cornerstones of effective treatments for BPD.

Rzucidlo SE, Shirk BJ. Trauma nursing: pediatric patients. *RN* 2004; 67(6):36-41; quiz 42.

Sa RC, Verbandt Y. Automated breath detection on long-duration signals using feedforward backpropagation artificial neural networks. *IEEE Trans Biomed Eng* 2002; 49(10):1130-41.

Abstract: A new breath-detection algorithm is presented, intended to automate the analysis of respiratory data acquired during sleep. The algorithm is based on two independent artificial neural networks (ANN(insp) and ANN(expi)) that recognize, in the original signal, windows of interest where the onset of inspiration and expiration occurs. Postprocessing consists in finding inside each of these windows of interest minimum and maximum corresponding to each inspiration and expiration. The ANN(insp) and ANN(expi) correctly determine respectively 98.0% and 98.7% of the desired windows, when compared with 29,820 inspirations and 29,819 expirations detected by a human expert, obtained from three entire-night recordings. Postprocessing allowed determination of inspiration and expiration onsets with a mean difference with respect to the same human expert of (mean +/- SD) 34 +/- 71 ms for inspiration and 5 +/- 46 ms for expiration. The method proved to be effective in detecting the onset of inspiration and expiration in full night continuous recordings. A comparison of five human experts performing the same classification task yielded that the automated algorithm was undifferentiable from these human experts, falling within the distribution of human expert results. Besides being applicable to adult respiratory volume data, the presented algorithm was also successfully applied to infant sleep data, consisting of uncalibrated rib cage and abdominal movement recordings. A comparison with two previously published algorithms for breath detection in respiratory volume signal shows that the presented algorithm has a higher specificity, while presenting similar or higher positive predictive values.

Saarlal KN, Hinman AR, Ross DA *et al.* All Kids Count 1991-2004: developing information systems to improve child health and the delivery of immunizations and preventive services. *J Public Health Manag Pract* 2004; Suppl:S3-15.

Abstract: The All Kids Count program began in late 1991 with funding from The Robert Wood Johnson Foundation. The purpose was to improve child health and the delivery of immunizations and preventive services through the development of health information systems. All Kids Count concluded in mid-2004 having worked directly with 38 state and local health agencies through its grant and Connections program. The lessons learned from the 13-year program are

applicable to other public health and medical care initiatives. Health information systems projects should: (1) involve stakeholders from the beginning, (2) recognize the complexity of establishing a population-based information system, (3) develop the policy/business/value case for information systems, (4) define the requirements of the system to support users' needs, (5) develop information systems according to current standards, (6) address common problems collaboratively, (7) plan for change, (8) plan boldly but build incrementally, (9) develop a good communications strategy, and (10) use the information (even if not perfect). Opportunities exist for public health agencies to share their experiences from developing immunization registries and integrated child health information systems and to develop collaborative approaches to improving the nation's health information infrastructure.

Sabin M, Lopes Cardozo B, Nackerud L, Kaiser R, Varese L. Factors associated with poor mental health among Guatemalan refugees living in Mexico 20 years after civil conflict. *JAMA* 2003; 290(5):635-42. Abstract: CONTEXT: From 1981 to 2001, 46 000 refugees who fled the 36-year civil conflict in Guatemala for Chiapas, Mexico were under the protection of the United Nations High Commissioner for Refugees. OBJECTIVES: To estimate the prevalence of mental illness and factors associated with poor mental health of underserved Guatemalan refugee communities located in Chiapas, Mexico, since 1981 and to assess need for mental health services. DESIGN, SETTING, AND PARTICIPANTS: Cross-sectional survey of 183 households in 5 Mayan refugee camps in Chiapas representing an estimated 1546 residents (adults and children) conducted November-December 2000. MAIN OUTCOME MEASURES: Symptom criteria of Posttraumatic Stress Disorder (PTSD), anxiety, and depression as measured by the Harvard Trauma Questionnaire and Hopkins Symptom Checklist-25 (Hopkins-25). RESULTS: One adult (aged > or =16 years) per household (n = 170 respondents) who agreed to participate was included in the analysis, representing an estimated 93% of households. All respondents reported experiencing at least 1 traumatic event with a mean of 8.3 traumatic events per individual. Of the respondents, 20 (11.8%) had all symptom criteria for PTSD. Of the 160 who completed the Hopkins Symptom Checklist-25, 87 (54.4%) had anxiety symptoms and 62 (38.8%) had symptoms of depression. Witnessing the disappearance of family members (adjusted odds ratio [AOR], 4.58; 95% confidence interval [CI], 1.35-15.50), being close to death (AOR, 4.19, 95% CI, 1.03-17.00), or living with 9 to 15 persons in the same home (AOR, 3.69; 95% CI, 1.19-11.39) were associated with symptoms of PTSD. There was a protective factor found for lacking sufficient food (AOR, 0.08; 95% CI, 0.01-0.59). Elevated anxiety symptoms were associated with witnessing a massacre (AOR, 10.63; 95% CI, 4.31-

26.22), being wounded (AOR, 3.22; 95% CI, 0.95-10.89), and experiencing 7 to 12 traumatic events (AOR, 2.67; 95% CI, 1.14-6.27) and 13 to 19 traumatic events (AOR, 2.26; 95% CI, 0.65-7.89). Elevated symptoms of depression were associated with being a woman (AOR, 3.64; 95% CI, 1.47-9.04), being widowed (AOR, 27.55; 95% CI, 2.54-299.27), being married (AOR, 1.93; 95% CI, 0.59-6.33), witnessing disappearances (AOR, 2.68; 95% CI, 1.16-6.19), experiencing 7 to 12 traumatic events (AOR, 1.57; 95% CI, 0.64-3.88), or experiencing 13 to 19 traumatic events (AOR, 7.44; 95% CI, 2.18-25.37). CONCLUSION: Psychiatric morbidity related to human rights violations, traumatic events, and refugee status was common among Guatemalan refugees surveyed 20 years after the Guatemalan civil conflict.

Sabol WJ, Coulton CJ, Korbin JE. Building community capacity for violence prevention. *J Interpers Violence* 2004; 19(3):322-40. Abstract: The capacity of communities to prevent violence is examined from three perspectives: youth violence, child maltreatment, and intimate partner violence. The analysis suggests that community social control and collective efficacy are significant protective factors for all three types of violence, but these need to be further distinguished for their relationships to private, parochial, and state controls. It is argued that strong interpersonal ties are not the only contributor to collective efficacy and violence prevention. Weak ties, including those outside the community, and organizational ties are also seen as necessary. Violence prevention programs should be structured in ways that contribute to the communities' own capacity to prevent violence.

Sachs BC, Gaillard WD. Organization of language networks in children: functional magnetic resonance imaging studies. *Curr Neurol Neurosci Rep* 2003; 3(2):157-62. Abstract: Functional magnetic resonance imaging (fMRI) is a relatively new neuroimaging procedure that has been used to study a wide variety of cognitive phenomena in adults, including attention, language, and memory. More recently, this technique has been successfully applied to pediatric populations as well. In particular, many investigators have employed fMRI as a tool to study language development in normal children. This paper reviews the current imaging research on the identification of cortex subserving components of language processing in young children. The literature suggests that fMRI can successfully identify regions of language cortex in children in much the same capacity as it can with adults, and that generally, adults and children show fundamental similarities in the patterns of activation. However, special considerations with pediatric imaging, paradigm design, and image analysis are also discussed.

Saeed MU, Parmar DN, Ohri R. The role of an ophthalmologist in suspected non-accidental injury. *Eye* 2003; 17(1):93-5.

Sahu G, Mohanty S, Dash JK. Vulnerable victims of sexual assault. *Med Sci Law* 2005; 45(3):256-60. Abstract: Sexual assault is one of the heinous crimes of present day society. Although it has always been evident, in recent times there has been a steady increase in the rate of sexual assault cases. The aim of this study was to identify the groups most at risk. Therefore it includes only cases of sex offences and sex offences with kidnapping. Information was obtained by interviewing the victims and accompanying persons, and from records submitted by the investigating officers. Our study reveals sexual assault commonly occurs among the age group of 16-19 years (60.8%), mostly at night (53.23%), inside the house (87%) and usually by a close acquaintance (61%). The majority of the victims were unmarried (84.7%), lived in rural areas (65.2%), were unemployed (93.5%), of less educated or illiterate groups (88%) and found to be mentally fit (97%). The victims were mostly drawn from low socio-economic groups.

Salamzadeh J, Wong IC, Hosker HS, Patel MG, Chrystyn H. The relationship between the quality of prescribing and practice appointment rates with asthma management data in those admitted to hospital due to an acute exacerbation. *Respir Med* 2005; 99(6):735-41. Abstract: Specific targeting of patients with a previous asthma hospitalisation could be more focused if predictors could be identified. This study was an observational retrospective analysis using ridge and linear multivariate regression analysis. Patient asthma management data were extracted from the hospital and general practice notes of those that had been admitted with an acute exacerbation of their asthma over a 5-year period. From the prescribing data, the annual doses of preventer (P) and reliever (R) medication were converted to defined daily doses then divided to give a P:R ratio. Preliminary statistical analysis was used to identify any association between either the P:R ratio or for the number of general practitioner (GP) practice appointments (PA) and their asthma management data. Multivariate regression analysis was applied to the P:R ratio and to PA to determine a model between each of these and asthma management data/events. GPs gave consent to access the data of 115 (out of 440) asthmatics, age >5 years, admitted to a district general hospital for asthma exacerbations between 1994 and 1998. The multivariate analysis revealed that PA was associated with oral prednisolone rescue courses (PRCs) and age whilst the P:R ratio was associated to PRCs and more reliever usage but not preventers. Patients with low preventer usage with respect to their reliever medication should be targeted for medication review as these were the patients prescribed more prednisolone courses and their increased PAs reflect this. This could decrease visits to the doctor and acute

exacerbations.

Salati R, Schiavulli O, Giammari G, Borgatti R. Checklist for the evaluation of low vision in uncooperative patients. *J Pediatr Ophthalmol Strabismus* 2001; 38(2):90-4.

Abstract: PURPOSE: To present a checklist for the evaluation of low vision in uncooperative patients; in this specific case, children with neurological deficits. METHOD: The checklist includes several behavioral indicators obtainable with a standard clinical examination. Each test is assigned a score (0=failure, 1=success). The final visual quotient score is obtained by dividing the partial score by the total number of tests performed. Eleven children with cerebral visual impairment were studied using behavioral and preferential looking techniques. RESULTS: Visual quotient was >0 in all patients, indicating that residual visual function was always detectable. Average visual quotient was 0.74. CONCLUSION: Visual quotient can be useful both for follow-up examinations and comparison and integration with other evaluation methods (behavioral and instrumental) of residual visual capacity. In particular, if combined with preferential looking techniques, visual quotient testing permits characterization of the entire spectrum of low vision.

Salazar JC. Pediatric clinical trial experience: government, child, parent and physician's perspective. *Pediatr Infect Dis J* 2003; 22(12):1124-7.

Abstract: In contrast to investigations in adults, investigation of drugs via clinical trials has been lacking in the pediatric population. Until recently there was little incentive on the part of the pharmaceutical industry to conduct clinical trials of new drugs in children. However, government legislation approved in the late 1990s has promoted efforts to investigate the effects of drugs in the treatment of a variety of children's diseases. Such data provide important and needed information on appropriate dosing, rates and types of adverse reactions and efficacy for treatment of pediatric illnesses. The conduct of clinical trials in children is dependent on a careful dialogue between the investigator, child and guardians wherein a detailed description of benefits vs. risks is conveyed. The focus of this paper is to summarize various perspectives on conducting clinical trials in children, including those of the government, the child, the parents or guardians and the investigator. Although children now have access to new medicines during the development process, their participation in clinical trials must still protect them from undue risk and secure their well being.

Salib E, Appleton T, Pembleton A. Elder abuse and elderly abusers. *Med Sci Law* 2002; 42(2):147-8.

Salloum A, Avery L, McClain RP. Group psychotherapy for adolescent survivors of homicide victims: a pilot study.

J Am Acad Child Adolesc Psychiatry 2001; 40(11):1261-7.

Abstract: OBJECTIVE: To conduct an exploratory study designed to evaluate the effectiveness of a time-limited psychotherapy group model to decrease traumatic symptoms among adolescent survivors of homicide victims. METHOD: Forty-five inner-city adolescents between the ages of 11 and 19 years participated in community-based, time-limited therapy groups that were specifically designed for youths who had a loved one die because of violence. The therapy groups were based on a 10-week treatment model for adolescent survivors of homicide victims with the goals of providing grief education, facilitating thoughts and feelings about grief, and reducing traumatic symptoms. RESULTS: On completion of group therapy, the adolescent participants reported an overall significant decrease in traumatic symptoms on an index of posttraumatic stress, especially in the areas of reexperiencing and avoidance symptoms. The mean difference between pre- and posttest was a 10.03 decrease in the sum of the Child PTSD Reaction Index scores (sig = .001). CONCLUSION: The results of this pilot study indicate that group therapy may be helpful in reducing PTSD symptoms among inner-city, African-American adolescent survivors of homicide victims. Although validity is limited by the lack of a comparison group, the authors suggest that such a brief trauma/grief psychotherapy group may be applicable for suburban and rural adolescent survivors of homicide victims as well. .

Salmon DA, Siegel AW. Religious and philosophical exemptions from vaccination requirements and lessons learned from conscientious objectors from conscription. Public Health Rep 2001; 116(4):289-95. Notes: GENERAL NOTE: KIE: 22 refs. GENERAL NOTE: KIE: KIE Bib: immunization; public health; treatment refusal/minors Abstract: All jurisdictions in the US require proof of vaccination for school entrance. Most states permit non-medical exemptions. Public health officials must balance the rights of individuals to choose whether or not to vaccinate their children with the individual and societal risks associated with choosing not to vaccinate (i.e., claiming an exemption). To assist the public health community in optimally reaching this balance, this analysis examines the constitutional basis of non-medical exemptions and examines policies governing conscientious objection to conscription as a possible model. The jurisprudence that the US Supreme Court has developed in cases in which religious beliefs conflict with public or state interests suggests that mandatory immunization against dangerous diseases does not violate the First Amendment right to free exercise of religion. Accordingly, states do not have a constitutional obligation to enact religious exemptions. Applying the model of conscientious objectors to conscription suggests that if states choose to offer nonmedical exemptions, they may be able to optimally

balance individual freedoms with public good by considering the sincerity of beliefs and requiring parents considering exemptions to attend individual educational counseling.

Saluja G, Iachan R, Scheidt PC, Overpeck MD, Sun W, Giedd JN. Prevalence of and risk factors for depressive symptoms among young adolescents. Arch Pediatr Adolesc Med 2004; 158(8):760-5. Abstract: OBJECTIVE: To determine the prevalence, risk factors, and risk behaviors associated with depressive symptoms in a nationally representative, cross-sectional sample of young adolescents. DESIGN: A school-based survey collected through self-administered questionnaires in grades 6, 8, and 10 in 1996. SETTING: Schools in the United States. PARTICIPANTS: 9863 students in grades 6, 8, and 10 (average ages, 11, 13, and 15). MAIN OUTCOME MEASURES: Depressive symptoms, substance use, somatic symptoms, scholastic behaviors, and involvement in bullying. RESULTS: Eighteen percent of youths reported symptoms of depression. A higher proportion of females (25%) reported depressive symptoms than males (10%). Prevalence of depressive symptoms increased by age for both males and females. Among American Indian youths, 29% reported depressive symptoms, as compared with 22% of Hispanic, 18% of white, 17% of Asian American, and 15% of African American youths. Youths who were frequently involved in bullying, either as perpetrators or as victims, were more than twice as likely to report depressive symptoms than those who were not involved in bullying. A significantly higher percentage of youths who reported using substances reported depressive symptoms as compared with other youths. Similarly, youths who reported experiencing somatic symptoms also reported significantly higher proportions of depressive symptoms than other youths. CONCLUSIONS: Depression is a substantial and largely unrecognized problem among young adolescents that warrants an increased need and opportunity for identification and intervention at the middle school level. Understanding differences in prevalence between males and females and among racial/ethnic groups may be important to the recognition and treatment of depression among youths.

Saluja G, Kotch J, Lee LC. Effects of child abuse and neglect: does social capital really matter? Arch Pediatr Adolesc Med 2003; 157(7):681-6. Abstract: OBJECTIVE: To explore whether social capital and social support moderate the relationship between child maltreatment and emotional and behavioral outcomes such as depression-anxiety and aggression in 6-year-old children. DESIGN: Data from Longitudinal Studies of Child Abuse and Neglect were used. Data were collected through interviews and questionnaires at the child's birth and at the age of 6 years. SETTING: General community. PARTICIPANTS: Two hundred fifteen maternal

caregivers of children at high risk for child abuse and neglect were included in this study. **MAIN OUTCOME MEASURES:** Depression-anxiety and aggression were measured through the Child Behavior Checklist. **RESULTS:** Among 5 potential effect modifiers (3 social capital constructs and 2 measures of social support), only 1 (instrumental support) significantly modified the relationship between maltreatment and child aggression. **CONCLUSIONS:** Social capital did not modify the relationship between child maltreatment and either aggression or depression-anxiety. This might be related to the fact that many previous studies looked at social capital ecologically, whereas this study uses individuals as the unit of analysis. The results of this study might also indicate that previous studies of social capital and health outcomes might actually be using social capital as a proxy for social support.

Salvi M, Dazzi D, Pellistri I, Neri F, Wall JR. Classification and prediction of the progression of thyroid-associated ophthalmopathy by an artificial neural network. *Ophthalmology* 2002; 109(9):1703-8. **Abstract:** **OBJECTIVE:** We have used an artificial neural network in an attempt to classify and predict the progression of thyroid-associated ophthalmopathy (TAO) at the first clinical examination. **DESIGN:** This retrospective comparative case series included a group of patients examined by the ophthalmologist only once because of the absence of signs of progressive disease (GR1), as subsequently monitored by an endocrinologist, and a group of patients on follow-up because of progressive disease (GR2). **PARTICIPANTS AND METHODS:** We examined 242 patients, of whom 207 were women and 35 were men. GR1 included 129 patients (257 eyes) who, on ophthalmologic assessment, were further classified as having no TAO (n = 53; GR1a) and only lid signs or inactive, stable TAO (n = 76; GR1b). GR2 included 113 patients (219 eyes). One hundred three normal subjects (205 eyes), 50 women and 53 men, were tested to provide normal ranges for proptosis values. We applied a model of back propagation neural network with 17 input variables, a training matrix of 414 observations, a randomly selected test group of 115 observations, and, as output, the progression of disease. The ophthalmologic assessment included (1) lid fissure measurement, (2) Hertel, (3) color vision, (4) cover test and Hess screen, (5) visual acuity, (6) tonometry, (7) fundus examination, (8) visual field, and (9) orbital computed tomography scan or ultrasonography. Other parameters included in the neural analysis were gender and age of the patients, their cigarette smoking, and the interval between follow-up visits. **RESULTS:** The prevalence of smokers among patients without TAO was significantly lower than that among those with TAO ( $P < 0.03$ ). Mean proptosis values (Hertel) were significantly different in GR1, in GR2, and in a group of normal eyes ( $P < 0.0001$ ), and the changes of values in consecutive measurements were associated with progression of the disease ( $P < 0.01$ ). Differences of

the proptosis values in the two groups of patients were not related to smoking. The neural network correctly classified 78.3% of 115 eyes (87 patients) and predicted TAO progression in 69.2% of 39 eyes (28 patients). **CONCLUSIONS:** In our opinion, neural network analysis can be successfully applied for classifying TAO and predicting progression at the first clinical examination.

Samms-Vaughan ME, Jackson MA, Ashley DE. Urban Jamaican children's exposure to community violence. *West Indian Med J* 2005; 54(1):14-21. **Abstract:** Exposure to violence in childhood is associated with aggression in adulthood. The high level of community violence in Jamaica is likely to expose Jamaican children to violence. There has been no detailed study of the exposure of Jamaican children to violence in their daily lives. Some 1674 urban 11-12-year-old children, previously part of a national birth cohort study, completed a questionnaire detailing their exposure to violence as witnesses, victims and aggressors. Their parents completed a socio-economic questionnaire. Jamaican children had high levels of exposure to physical violence. A quarter of the children had witnessed severe acts of physical violence such as robbery, shooting and gang wars, a fifth had been victims of serious threats or robbery and one in every twelve had been stabbed. Children reported being least exposed to sexual violence and to being shot at. Robbery was an almost universal experience affecting children from all schools and socio-economic groups. The single commonest experience as a victim of violence was the loss of a family member or close friend to murder, affecting 36.8% of children. Children's experiences of witnessing violence occurred chiefly in their communities but their personal experiences of violence occurred at school. Boys and children attending primary school had greater exposure to violence as witnesses and victims. Socio-economic status discriminated exposure to physical violence as witnesses but not as victims. Intervention strategies to reduce children's exposure to violence should include community education on the impact of exposure to violence on children, particularly the loss of a significant person, and the development of a range of school-based violence prevention programmes.

Samuel PR, Ranta M. A paediatric otolaryngology pre-admission assessment clinic audited. *J Laryngol Otol* 2001; 115(9):723-6. **Abstract:** Pre-admission clinics are becoming increasingly popular for surgical specialties with a quick turnover as they aid waiting list management and reduce non-attender rates for surgery. As paediatric patients have a high rate of non-attendance, we performed a retrospective audit of otolaryngology paediatric pre-admission assessment clinic notes for June to October 1998 (n = 363). The attendance rate for the clinic was 97 per cent. Of the children who attended the clinic, 90 per cent had their operation as

planned, complications occurred in 2.9 per cent. The operation date was delayed in 20 patients, in 11 patients no cause for the delay was given in the case notes. As a result of this audit, the Senior House Officer sees the patient on the day of admission rather than in the pre-admission clinic, which is staffed by nurses.

Samuelson JL, Buehler JW, Norris D, Sadek R. Maternal characteristics associated with place of delivery and neonatal mortality rates among very-low-birthweight infants, Georgia. *Paediatr Perinat Epidemiol* 2002; 16(4):305-13.

Abstract: To determine whether the Healthy People 2000 objective to deliver very-low-birthweight (VLBW) infants at subspecialty perinatal care centres was met, and if improvements in the regional perinatal care system could reduce neonatal mortality further for 2010, we examined place of delivery for VLBW infants, associated maternal characteristics and the potential impact on neonatal mortality. We used linked birth and death records for the 1994-96 Georgia VLBW (i.e. 500-1499 g) birth cohorts. Among 4770 VLBW infants, 77% were delivered at hospitals providing subspecialty perinatal care. The strongest predictor of birth hospital level was the mother's county of residence, defined using three levels: residence in a county with a subspecialty hospital, residence in a county adjacent to one with such a hospital or residence in a non-adjacent county. Eighty-nine per cent of infants born to women who resided in counties with subspecialty care hospitals delivered at such hospitals, compared with 53% of infants born to women who resided in a non-adjacent county. Women were also more likely to deliver outside subspecialty care if they had less than adequate prenatal care [adjusted odds ratio (AOR) 1.5, P-value = 0.0001]. The neonatal mortality rate varied by level of perinatal care at the birth hospital from 132.1/1000 to 283/1000 live births, with the highest death rate for infants born at hospitals offering the lowest level of care. Assuming that the differences in mortality were due to care level of the birth hospital, potentially 16-23% of neonatal deaths among VLBW infants could have been prevented if 90% of infants born outside subspecialty care were delivered at the recommended level. These findings suggest that a state's support of strong, collaborative, regional perinatal care networks is required to ensure that high-risk women and infants receive optimal health care. Improved access to recommended care levels should further reduce neonatal mortality until interventions are identified to prevent VLBW births.

Samuelson LK. Statistical regularities in vocabulary guide language acquisition in connectionist models and 15-20-month-olds. *Dev Psychol* 2002; 38(6):1016-37. Abstract: This research tested the hypothesis that young children's bias to generalize names for solid objects by shape is the product of statistical regularities

among nouns in the early productive vocabulary. Data from a 4-layer Hopfield network suggested that the statistical regularities in the early noun vocabulary are strong enough to create a shape bias, and that the shape bias is overgeneralized to nonsolid stimuli. A 2nd simulation suggested that this overgeneralization is due to the dominance of names for shape-based categories in the early noun vocabulary. Two subsequent longitudinal experiments tested whether it is possible to create word learning biases in children. Children 15-20 months old were given intensive naming experiences with 12 noun categories typical of the types of categories children learn to name early. The children developed a precocious shape bias that was overgeneralized to naming nonsolid substances; they also showed accelerated vocabulary development. Children taught an atypical set of nouns or no new nouns did not develop a shape bias and did not show accelerated vocabulary development.

Sanchez-Gimeno J, Martin-Carpi J, Martinez-Laborda S, Carrasco-Lorente S, Abenia-Uson P, Lopez-Pison J. [Lumbar puncture and early neuroimaging in complex febrile seizures. Report of a case of shaken infant syndrome]. *Rev Neurol* 2003; 36(4):351-4. Abstract: INTRODUCTION: Febrile convulsions are one of the most frequent pathologies seen in paediatric emergencies. The diagnosis of febrile seizures is clinico evolutionary and is easily established once the acute process is overcome and a normal state is restored in the child. The differential diagnosis is established with the processes that associate fever and convulsions in children between the ages of 1 month and 6 years, many of which require specific treatment. Certain complementary examinations, essentially a blood test, lumbar puncture and neuroimaging, are needed to identify them. Shaken infant syndrome is a form of physical abuse which includes the presence of intracranial traumatic injury, retinal haemorrhage and, in general, the absence of other physical signs of traumatic injury in the child. CASE REPORT: An 8 month old infant who presented a convulsive seizure on the left side of the body which coincided with an axillary temperature of 38 C that remitted with intravenous diazepam 40 minutes after onset. An early cranial computerised tomography (CT) scan led to a diagnosis of shaken infant syndrome. DISCUSSION: This case constitutes an argument in favour of performing an early cranial CT scan in complex febrile convulsions and in prolonged or partial non provoked seizures. We highlight the risks involved in performing a lumbar puncture in the absence of suspected non complicated acute bacterial meningitis. The diagnostic usefulness of an early CT scan in diagnosing such an important problem as shaken infant syndrome must also be noted, due to the risk of repetition and its high morbidity and mortality rates.

Sanders LM, Robinson TN, Forster LQ, Plax K, Brosco JP, Brito A. Evidence-based community pediatrics:

building a bridge from bedside to neighborhood. *Pediatrics* 2005; 115(4 Suppl):1142-7. Abstract: The American Academy of Pediatrics policy statement "The Pediatrician's Role in Community Pediatrics" encourages all pediatricians to partner with their communities to create and disseminate innovative programs that improve child health. This article describes 4 pillars of a bridge to evidence-based community pediatrics for pediatricians interested in pursuing effective community action: (1) collaborate with the community to establish a specific, short-term, health-related goal; (2) identify evidence-based best practice(s) for achieving the shared goal; (3) collaborate with the community to adapt this best practice to the community's unique assets and constraints; and (4) evaluate the project by using appropriate expertise. Practical elements of each pillar are described and illustrated by specific examples from community-based efforts of pediatricians and are accompanied by specific resources to aid pediatricians in their future community health work.

Sanders MR. Parenting interventions and the prevention of serious mental health problems in children. *Med J Aust* 2002; 177 Suppl:S87-92. Abstract: The reduction of coercive or inadequate parenting is essential if the mental health status of Australian children and adolescents is to be improved. Of the available approaches that address parenting practices, behavioural family interventions have the strongest empirical support and are effective in reducing parenting practices that contribute to the development of behavioural and emotional problems in children. However, only a small proportion of parents access such interventions. A comprehensive multilevel, evidence-based parenting and family support strategy needs to be implemented on a wide scale to reduce the prevalence of mental health problems in children and youth. The Triple P - Positive Parenting Program is an example of a population-level strategy that can be used to improve the mental health status of children and their parents.

Sandi L, Diaz A, Uglade F. Drug use and associated factors among rural adolescents in Costa Rica. *Subst Use Misuse* 2002; 37(5-7):599-611. Abstract: The objectives of this study, carried out in 1995, were to assess both licit and illicit substance use among rural male and female Costa Rican adolescents, and associated health, psychological, and psychosocial problems. A sample of 304 students from rural schools was randomly selected. The mean age for females was 14.7 years (S.D. = 1.71), and for males was 14.4 years (S.D. = 1.62). The data were collected using the Latin-American version of Drug Use Screening Inventory (DUSI). Results showed a high prevalence of past-year alcohol use for both males and females (56.6% and 47.4%, respectively), and a lower prevalence of past-year tobacco use (44.0% and 7.7%). There results also showed a low level of use of solvent inhalants and

benzodiazepines. In terms of illicit drugs, males preferred cocaine and marijuana, while females only reported amphetamine use. An analysis of adolescent functioning showed differences among alcohol users and nonusers in behavior patterns and peer relationships. However, no significant differences were found regarding rebellion, depression, and social isolation. The implications of these results are discussed, along with the importance of enhancing prevention, as well as early detection and intervention.

Sandoval-Priego AA, Reyes-Morales H, Perez-Cuevas R, Abrego-Blas R, Orrico-Torres ES. [Family life strategies and their relation with malnutrition in children under 2 years old]. *Salud Publica Mex* 2002; 44(1):41-9.

Abstract: OBJECTIVE: To identify the role of family life strategies on malnutrition in children aged 6-23 months of age. MATERIAL AND METHODS: This case-control study was conducted in 1998 in the municipality of Teolocholco, State of Tlaxcala, Mexico, among families with children aged 6-23 months of age. The sample was conformed by 105 cases and 210 controls. Family life strategies were grouped into five types: family composition, means and distribution of family income, family and social networks, and life preservation strategies. Malnutrition was classified according to height for age. Data were analyzed using logistic regression to obtain odds ratios and 95% confidence intervals. RESULTS: Data were collected from 605 families, for a total of 445 controls and 160 cases. The predictive model included mother's schooling, overcrowding, time elapsed between childbirths, per capita monthly income, and time devoted to child-rearing activities. CONCLUSIONS: Family life strategies determine children's nutritional status; understanding the influence of the family on the children's health status is necessary to develop effective programs aimed at improving the nutritional status of children.

Sant'Anna A, Aerts D, Lopes MJ. [Adolescent homicide victims in Southern Brazil: situations of vulnerability as reported by families]. *Cad Saude Publica* 2005; 21(1):120-9.

Abstract: This study focused on homicide deaths of adolescents (ages 10 to 19 years) in Porto Alegre, Rio Grande do Sul, Brazil, in 1997. Data were obtained from the Mortality Information System (SIM) of the Municipal Health Department. Families were visited at the addresses found on death certificates and were interviewed by two researchers. Of the 68 cases selected, 57 families were visited; eight families refused to be interviewed, and three addresses were not

- found. Most of the adolescents were socially vulnerable, as indicated by low per capita income and parental educational level; 78.9% had dropped out of school. Males were the predominant victims of adolescent homicide deaths (91.2%). Behavioral vulnerability was demonstrated as follows: 40.4% of the adolescents consumed alcoholic beverages and 45.6% illicit drugs, and 58.6% had criminal records or a history of custody at FEBEM (the State Juvenile Custody Facilities) or police arrests. The study highlights the importance of coordinating actions among different sectors to reach adolescents both at home and in the schools and communities.
- Sant'Anna AR, Lopes MJ. Homicides among teenagers in the city of Porto Alegre, Rio Grande do Sul State, Brazil: vulnerability, susceptibility, and gender cultures. *Cad Saude Publica* 2002; 18(6):1509-17. Abstract: The authors present a quantitative and qualitative study on homicides among teenagers in Porto Alegre, Rio Grande do Sul State, Brazil, based on a historical series during the 1990s and the life and death histories in this group, with a special focus on 1997. In that year there were 68 homicides in which the victims were from 10 to 19 years old. Of the 68, 62 were males and only 6 females, or a ratio of 10:1, showing that young males are more vulnerable and susceptible to being murdered. The data indicate that cause of death is influenced by gender culture and that homicides are based on power and status symbols characterizing a kind of virility. This expression of virility in the shaping of violence also appears in the domination of the female body observed in homicides with young women as the victims. The life and death histories of these teenagers highlight the pertinence of the gender-based analysis as a theoretical-analytical category, in addition to analyses considering socioeconomic aspects and social inequity.

- Sarimski K. Behavioural and emotional characteristics in children with Sotos syndrome and learning disabilities. *Dev Med Child Neurol* 2003; 45(3):172-8. Abstract: In contrast to physical characteristics, the developmental and behavioural characteristics of children with Sotos syndrome are not well documented. Data from a survey of 27 children (17 males and 10 females; mean age 10 years 7 months; range 6 to 15 years) with mild and moderate learning disabilities were obtained concerning school placement, social networks, adaptive competence, and behavioural problems and compared with a control group matched for cognitive level and age. Ten children attended a mainstream school (with remedial assistance), eight were placed in a school for children with learning disabilities, nine children attended other special schools. Social contact problems and anxious behaviour were reported as the most prominent characteristics of children with Sotos syndrome. Some implications for psychological counselling and educational support are discussed.

- Sarnaik AP, Daphtary K, Sarnaik AA. Ethical issues in pediatric intensive care in developing countries: combining western technology and eastern wisdom. *Indian J Pediatr* 2005; 72(4):339-42. Abstract: Application of traditional ethical principles in developing countries may not, indeed should not, conform to the western philosophy and ideology. The principle of distributive justice is of utmost importance when critical resources are scarce. There is no ethical imperative, nor is one followed even in the most advanced countries, that every citizen is entitled to the very best available care. However, a society must establish a uniform code of ethics that can be applied nationally, whereby all citizens are eligible for a minimum acceptable level of care. The traditional principles of autonomy, beneficence, nonmaleficence and justice are still applicable in structuring an ethical framework that is most suited for the country's needs and resources.

Abstract: The United States has made progress in decreasing the black-white gap in civil rights, housing, education, and income since 1960, but health inequalities persist. We examined trends in black-white standardized mortality ratios (SMRs) for each age-sex group from 1960 to 2000. The black-white gap measured by SMR changed very little between 1960 and 2000 and actually worsened for infants and for African American men age thirty-five and older. In contrast, SMR improved in African American women. Using 2002 data, an estimated 83,570 excess deaths each year could be prevented in the United States if this black-white mortality gap could be eliminated.

Saunders RP, Abraham MR, Crosby MJ, Thomas K, Edwards WH. Evaluation and development of potentially better practices for improving family-centered care in neonatal intensive care units. *Pediatrics* 2003; 111(4 Pt 2):e437-49. Abstract: OBJECTIVE: Technological and scientific advances have progressively decreased neonatal morbidity and mortality. Less attention has been given to meeting the psychosocial needs of the infant and family than on meeting the infant's physical needs. Parents' participation in making decisions and caring for their child has often been limited. Environments designed for efficient technological care may not be optimal for nurturing the growth and development of sick neonates or their families. Eleven centers collaborating on quality improvement tried to make the care of families better by focusing on understanding and improving family-centered care. METHODS: Through internal process analysis, review of the evidence, collaborative learning, and benchmarking site visits to centers of excellence in family-centered care, a list of potentially better practices was developed. Choice of which practices to implement and methods of implementation were center specific. Improvement goals were in 3 areas: parent-reported outcomes, staff beliefs and practices, and clinical outcomes in length of stay and feeding practices. Measurement tools for the first 2 areas were developed and pilots were conducted. RESULTS: Length of stay and feeding outcomes were not different before the collaboration (1998) and at the formal end of the collaboration (2000). CONCLUSIONS: Prospective parent-reported outcomes are being collected, and the staff beliefs and practices questionnaire will be repeated in all centers to determine the impact of the project in those areas.

Sauzeon H, Lestage P, Raboutet C, N'Kaoua B, Clavierie B. Verbal fluency output in children aged 7-16 as a function of the production criterion: qualitative analysis of clustering, switching processes, and semantic network exploitation. *Brain Lang* 2004; 89(1):192-202. Abstract: Developmental changes in children's verbal fluency were explored in this study. One hundred and forty children aged from 7 to 16 completed four verbal fluency tasks, each with a different the production criterion (letter, sound, semantic, and free). The age differences were analyzed both in terms of number of words produced, and clustering, switching, and semantic network exploration. Analysis of the number of words produced showed a larger difference between the 7-8- and the 9-10-year-olds in semantic than in letter fluency, but this difference gradually disappeared with increasing age for semantic fluency while remaining constant for letter fluency. In letter fluency production, age modified both the number of switches and clusters formed whereas in semantic fluency tasks, only cluster size changed with age. Concerning the semantic network exploration indicators derived from

the supermarket fluency task, the number of categories sampled increased from 11 to 12 years, but efficient semantic exploitation occurred only after the age of 13-14 years. These results are discussed in terms of the development of strategic retrieval components and categorical knowledge.

Savvidou I, Bozikas VP, Hatzigeleki S, Karavatos A. Narratives about their children by mothers hospitalized on a psychiatric unit. *Fam Process* 2003; 42(3):391-402.

Abstract: The diagnosis of "mental illness" is accompanied by negative implications regarding a person's competence. Self- and other-descriptions about the "patient" are embedded within broader cultural and societal discourses, influencing his/her relationships. The parental role seems to be one of the most sensitive, especially for women. Mothers hospitalized in psychiatric units often have to separate themselves from their children either temporarily, during hospitalization, or permanently, after a loss of custody. However, many studies have shown that mothering remains important for them. We interviewed 20 women, inpatients on a psychiatric unit and mothers of 3.5-18-year-old children, recording their narratives about their children and exploring their thoughts and understanding of the concepts of motherhood and mental illness. We also explored the way in which the mother-child dyad interacted with the family and its social context. Most mothers had a consistent and coherent narrative about their children and they had certain expectations of them. The mother-child bond was strong, even when the children had been removed from their mothers' custody. However, mothers were facing great difficulties with their partner and with the broader family context. Also, the social discourses regarding mental illness, (e.g., violence and incapability for mothering), were extremely oppressive for these women. They felt that they were the victims of societal attitudes even before they became pregnant. These findings suggest the importance of listening to the voices of these women; acknowledging their competence in the therapeutic context; involving them with their families, and in legal and social contexts; and in planning supportive programs for them.

Sayed SA. Baby doe redux? The Department of Health and Human Services and the Born-Alive Infants Protection Act of 2002: a cautionary note on normative neonatal practice. *Pediatrics* 2005; 116(4):e576-85. Abstract: The Born-Alive Infants Protection Act (BAIPA), passed by Congress in 2002, has attracted little publicity. Its purposes were, in part, "to repudiate the flawed notion that a child's entitlement to the protections of the law is dependent on whether that child's mother or others want him or her." Understood as antiabortion rhetoric, the bill raised little concern among physicians at the time of legislative hearings and passed in both Houses by overwhelming majorities, hardly suggesting contentious legislation. After its signing into law, the Neonatal Resuscitation Program (NRP) Steering Committee issued an opinion stating that "[BAIPA] should not in any way affect the approach that physicians currently follow with respect to the extremely premature infant." This interpretation of the law, however, may have been short sighted. In April 2005, the US Department of Health and Human Services (DHHS) brought life to the BAIPA, announcing: "As a matter of law and policy, [DHHS] will investigate all circumstances where individuals and entities are reported to be withholding medical care from an infant born alive in potential violation of federal statutes." The agency issued instructions to state officials on how the definitional provision within the BAIPA interacts with the Emergency Medical Treatment and Labor Act (EMTALA) and the Child Abuse Prevention and Treatment Act (CAPTA). These interagency memoranda potentially resurrect dormant governmental oversight of newborn-treatment decisions and thus may have influence over normative neonatal practice. Under the BAIPA, the DHHS interprets EMTALA to protect all "born-alive" infants; hospitals and physicians violating regulatory requirements face agency-sanctioned monetary penalties or a "private right of action by any individual harmed as a direct result." According to its memorandum, the DHHS will investigate allegations of EMTALA violations whenever it finds evidence that a newborn was not provided with at least a medical screening examination under circumstances in which a "prudent layperson observer" could conclude from the infant's "appearance or behavior" that it was "suffering from an emergency medical condition." The memorandum fails to clarify which observers qualify as prudent, what infant appearance or behavior is relevant, or what defines an emergency medical condition. Because these evaluative criteria are not constrained by reference to relevant standards of medical care, the agency arguably substitutes a nonprofessional's presumed sagacious assessment of

survivability for reasonable medical judgment. Indeed, under a straightforward reading of the instruction, a family member could conceivably trigger an investigation after observing a relative deliver a 20-week fetus who maintains a heartbeat for an hour before its death. Most physicians would not consider this an emergency medical condition and, rather than perform a screening examination, would provide comfort for the newborn and support for the family. The guideline, however, does not state that professional acumen trumps the layperson's observations in these instances; thus, physicians are left unclear about whether screening examinations are required for all newborns regardless of a priori, reasoned considerations of survivability. In this context, the NRP Steering Committee opinion states that "at the time of delivery... the medical condition and prognosis of the newly born infant should be assessed. At that point decisions about withholding or discontinuing medical treatment that is considered futile may be considered by... providers in conjunction with the parents acting in the best interest of their child." However, most pediatricians skilled in screening and resuscitation are not currently called on to perform this function when the gestational age of a nonviable fetus is reasonably certain before delivery. If under the law screening is now required at any gestational age, professional procedure immediately after previable births may need modification. More worrisome, threatened aggressive investigations of alleged EMTALA violations at the soft edges of viability, where futility remains a matter of debate, jeopardize the normative ethical practice of offering discretionary palliative care. The DHHS sent its other instruction to state child protective services agencies responsible for implementing CAPTA regulations; it reiterates the limited situations in which physicians may withhold medical treatment from infants and reemphasizes the local role of "individuals within health care facilities" to notify authorities of suspected infractions. Its real import, however, is insistence on local execution of legal remedies to prevent nontreatment decisions deemed impermissible by the 1984 Baby Doe rules. Because this new directive encourages governmental oversight of treatment decisions involving imperiled newborns, a period of benign regulatory neglect seems to be over. The federal CAPTA rules arguably remove quality-of-life considerations from the decision-making calculus and therefore may conflict with the best-interests paradigm advocated by the American Academy of Pediatrics and NRP. How courts will respond to the DHHS interpretation of EMTALA and CAPTA under the BAIPA remains unclear. Federal courts have yet to authoritatively examine alleged EMTALA violations involving newborn treatment decisions at the limits of viability. The Wisconsin Supreme Court has permitted an EMTALA claim to go to trial where physicians allegedly did not screen or resuscitate a 22-week newborn delivered in an emergency department, and a lower appellate court has relied on CAPTA to hold that

parents do not possess the right to choose against resuscitating an extremely premature newborn. The Texas Supreme Court recently granted physicians the paternalistic prerogative to resuscitate imperiled newborns without attention to parental preference under a common law doctrine of "emergent circumstances." These judicial decisions undermine the ethical discretion parents are typically afforded in decision-making before and after delivery in these morally complex situations. The DHHS interpretation of the BAIPA may encourage jurisdictional creep of these kinds of pronouncements as the agency seeks to expand legal protections for born-alive infants. The US Supreme Court has stated that "courts must presume that a legislature says in a statute what it means and means in a statute what it says there"; thus, judges interpret law by analyzing "concrete statutory language, not by reference to abstract notions of generalized legislative intent." The BAIPA indiscriminately defines "born alive" to include an infant "at any stage of development... regardless of whether the expulsion or extraction occurs as a result of natural or induced labor, cesarean section, or induced abortion," and it makes no reference to standards of care or best interests, nor does it specifically protect a parent's decision-making authority. Under the law's strict logic, an 18-week miscarried fetus with a detectable heart beat after delivery is entitled to the full protections of the law as determined by "any Act of Congress, or any ruling, regulation, or interpretation of the various administrative bureaus and agencies." Before concluding that the BAIPA would not affect normative neonatal practice, the NRP Steering Committee should have analyzed the act's actual statutory language and avoided relying heavily on imprecise legislative intent. The BAIPA's congressional sponsors did claim that the law "will not mandate medical treatment where none is currently indicated," but such political rhetoric is often not sufficient to render law innocuous years after separation from its legislative history. Besides, nowhere in the House record does the majority explicitly acknowledge that discretion to decide the fate of imperiled newborns invests in parents, in consultation with physicians; indeed, the bill's stated purpose was to repudiate that notion. At best, legislators recognized that physicians disagree about the efficacy of resuscitating at the limits of viability, and therefore the current standard of care permits doctors to deem resuscitation a futile endeavor. However, judges may resist characterizing resuscitation as futile, given its poor analytical fit, and substantial public-policy concerns regarding discrimination against future disabled individuals could easily tip a court to preserve incipient, at least, physiologic life under the BAIPA's all-encompassing definition of born alive.

Sayers BM, Angulo J. A new explanatory model of an SIR disease epidemic: a knowledge-based, probabilistic

approach to epidemic analysis. *Scand J Infect Dis* 2005; 37(1):55-60.

Abstract: A new explanatory model for epidemic analysis is presented; it has a knowledge based component and a probabilistic computational component. The former assembles details of household characteristics, social networks and connectivity in the community--'knowledge'--which is used to determine the structure of the computational component. The latter links individuals and households through statistically-defined opportunities for contacts and, by repeated trials, determines an average longitudinal time course (epidemic curve) of the simulated infection as it spreads through the community from inception to extinction of the epidemic. The model thus aims to describe the epidemic itself, rather than any abstraction of it. In application to a 1955-56, self-contained epidemic of an SIR disease, variola minor, the model generates 1 dominant longitudinal pattern that matches closely the epidemic curve of observed daily case rates; it is suggested that other patterns indicate different ways in which the epidemic might have evolved. The model can be used to show how differing community characteristics would affect the simulated epidemic.

Sazonov E, Sazonova N, Schuckers S, Neuman M. Activity-based sleep-wake identification in infants. *Physiol Meas* 2004; 25(5):1291-304.

Notes: CORPORATE NAME: CHIME Study Group  
Abstract: Actigraphy offers one of the best-known alternatives to polysomnography for sleep-wake identification. The advantages of actigraphy include high accuracy, simplicity of use and low intrusiveness. These features allow the use of actigraphy for determining sleep-wake states in such highly sensitive groups as infants. This study utilizes a motion sensor (accelerometer) for a dual purpose: to determine an infant's position in the crib and to identify sleep-wake states. The accelerometer was positioned over the sacral region on the infant's diaper, unlike commonly used attachment to an ankle. Opposed to broadly used discriminant analysis, this study utilized logistic regression and neural networks as predictors. The accuracy of predicted sleep-wake states was established in comparison to the sleep-wake states recorded by technicians in a polysomnograph study. Both statistical and neural predictors of this study provide an accuracy of approximately 77-92% which is comparable to similar studies achieving prediction rates of 85-95%, thus validating the suggested methodology. The results support the use of body motion as a simple and reliable method for determining sleep-wake states in infants. Nonlinear mapping capabilities of the neural network benefit the accuracy of sleep-wake state identification. Utilization of the accelerometer for the dual purpose allows us to minimize intrusiveness of home infant monitors.

Scerif G, Karmiloff-Smith A. The dawn of cognitive genetics? Crucial developmental caveats. *Trends Cogn Sci* 2005; 9(3):126-35.  
Abstract: Attempts to bridge genetics and cognition are rapidly coming to the forefront of cognitive neuroscience. It is therefore crucial to evaluate the current state of knowledge about disorders of known genetic origin as a way of assessing whether, and if so how, links between genotype and cognitive phenotype can be drawn, however indirect these links might be. We review recent empirical findings from research on genetic disorders at three levels of description--cognitive, neural systems, and cellular--that caution against simple genotype-phenotype mappings at all levels. Most importantly, interdisciplinary efforts to integrate human genetics and cognition will need to operationalize the mechanisms driving both typical and atypical developmental processes over time.

Schaeffer CM, Petras H, Ialongo N, Poduska J, Kellam S. Modeling growth in boys' aggressive behavior across elementary school: links to later criminal involvement, conduct disorder, and antisocial personality disorder. *Dev Psychol* 2003; 39(6):1020-35.  
Abstract: The present study used general growth mixture modeling to identify pathways of antisocial behavior development within an epidemiological sample of urban, primarily African American boys. Teacher-rated aggression, measured longitudinally from 1st to 7th grade, was used to define growth trajectories. Three high-risk trajectories (chronic high, moderate, and increasing aggression) and one low-risk trajectory (stable low aggression) were found. Boys with chronic high and increasing trajectories were at increased risk for conduct disorder, juvenile and adult arrest, and antisocial personality disorder. Concentration problems were highest among boys with a chronic high trajectory and also differentiated boys with increasing aggression from boys with stable low aggression. Peer rejection was highest among boys with chronic high aggression. Interventions with boys with distinct patterns of aggression are discussed.

Schaffer M. More cover-ups, more shame. *US News World Rep* 2002; 132(19):46, 48.

Scharer K, Jones DS. Child psychiatric hospitalization: the last resort. *Issues Ment Health Nurs* 2004; 25(1):79-101.  
Abstract: The purpose of this study was to describe how parents manage the experience of hospitalizing their school-aged child in a psychiatric unit. Grounded theory methodology was used. Thirty-eight parents participated. Data were collected by interviews.

Analysis was done using the constant comparative method. The basic social problem identified was the escalating behavior of the child. The child's behavior included self-injurious behavior or violence toward others. The core concept was "hospitalization, the last resort." Parents' management of the experience varied based on many factors including whether this was the child's first psychiatric hospitalization, the distance from the hospital to their home, their trust of staff members, sources of support, and their definition of the situation.

Scharff JL, Broida JP, Conway K, Yue A. The interaction of parental alcoholism, adaptation role, and familial dysfunction. *Addict Behav* 2004; 29(3):575-81.  
Abstract: Many people believe that parental alcoholism has adverse consequences on children--some research fails to support this hypothesis. Familial dysfunction is often regarded as having a more important impact on adults, perhaps because of a failure to recognize that adult children of alcoholics (ACOAs) may have adopted more than one coping strategy. The present study investigated within-group differences in psychological symptomology as measured by the Millon Clinical Multiaxial Inventory (MCMI). ACOAs, were compared by roles (Hero, Mascot, Lost Child, and Scapegoat) to non-ACOAs as measured by familial dysfunction and roles. MANOVA indicated significant main effects of dysfunction, role, ACOA, and an interaction of role and ACOA. Failures to recognize the impact of parental alcoholism may be caused by multiple adaptation strategies.

Schechter DS, Zeanah CH Jr, Myers MM *et al.* Psychobiological dysregulation in violence-exposed mothers: salivary cortisol of mothers with very young children pre- and post-separation stress. *Bull Menninger Clin* 2004; 68(4):319-36.  
Abstract: To understand the determinants of frightening/frightened and other atypical maternal behavior, the authors studied a sample of 41 inner-city mothers of very young children (ages 8-50 months), the mothers of whom had lifetime histories of interpersonal violent trauma (i.e., physical or sexual abuse, and domestic violence) and related posttraumatic stress. METHOD: The authors measured (1) maternal salivary cortisol levels before and 30 minutes after a videotaped play paradigm with their children, involving two separations and reunions; and (2) cortisol reactivity 30 minutes after separation stress. Data were analyzed using Pearson bivariate correlations, ANOVA, and multiple linear regressions. RESULTS: Salivary cortisol "baseline" values were significantly negatively correlated with childhood interpersonal violent trauma severity (i.e., trauma severity prior to age 16). However, cortisol reactivity was not significantly correlated with interpersonal violent trauma severity at this level of analysis. Although baseline salivary cortisol values were not significantly correlated with current overall psychiatric or depressive symptoms,

they were negatively correlated with severity of current posttraumatic stress symptoms (PTSS) and with dissociative symptoms. Neither dimensions of negativity nor distortion of maternal attributions showed any significant association with prestress or poststress salivary cortisol levels. Salivary cortisol baseline was negatively correlated with atypical maternal behavior via measurement of the level of disrupted communication, at a trend-level of significance. CONCLUSIONS: Violent trauma-associated dysregulation of the hypothalamic-pituitary-adrenal (HPA) axis may be a marker for increased risk for intergenerational transmission via parenting behavior with young children. Low salivary cortisol prior to separation stress and blunted cortisol reactivity to separation may also be markers for posttraumatic stress.

Scheeringa MS, Zeanah CH, Myers L, Putnam F. Heart period and variability findings in preschool children with posttraumatic stress symptoms. *Biol Psychiatry* 2004; 55(7):685-91. Abstract: BACKGROUND: Traumatic experiences for young children might result in profound neurodevelopmental changes, compared with adults. Our aim was to examine autonomic control of heart rate in traumatized young children. METHODS: Sixty-two children who had suffered traumas and 62 nontraumatized control children, aged 20 months to 6 years, were assessed for posttraumatic stress disorder (PTSD) symptoms, interbeat interval, respiratory sinus arrhythmia (RSA), family rehearsal of the trauma, and parent-child relationship quality. RESULTS: Traumatized children with PTSD and traumatized children without PTSD both had decreased heart period in response to a trauma stimulus relative to the nontraumatized group (both  $p < .0167$ ). there was no main effect for RSA change scores, however, there was a significant interaction effect between parental positive discipline with PTSD symptoms and RSA. The most sympathetic children had decreased RSA during the trauma stimulus when they had caregivers with less positive discipline during a clean-up and family rehearsal with PTSD symptoms. CONCLUSIONS: These findings underscore that psychopathology in young children ought to be assessed in the context of psychophysiology and parent-child relationship to optimally understand the mechanisms of maladaptation during this complex developmental period.

Scheibner V. Response to Leask and McIntyre's attack on myself as a public opponent of vaccination. *Vaccine* 2003; 22(1):vi-ix.

Scheidlinger S, Kahn GB. In the aftermath of September 11: group interventions with traumatized children revisited. *Int J Group Psychother* 2005; 55(3):335-54. Abstract: The terrorist attacks of September 11, 2001,

affected thousands of children psychologically, necessitating the mobilization of multifaceted mental health interventions in an ecological context. This paper reviews the major role of large and small group modalities in this challenging effort, with many of them based on earlier group work with child-victims of trauma.

Schenarts PJ. Three-year-old boy with burn wound sepsis: a challenge to the ethics of a responsible surgeon. *Curr Surg* 2004; 61(3):245-6. Notes: GENERAL NOTE: KIE: KIE Bib: patient care/minors

Schetinin V, Schult J. The combined technique for detection of artifacts in clinical electroencephalograms of sleeping newborns. *IEEE Trans Inf Technol Biomed* 2004; 8(1):28-35. Abstract: In this paper, we describe a new method combining the polynomial neural network and decision tree techniques in order to derive comprehensible classification rules from clinical electroencephalograms (EEGs) recorded from sleeping newborns. These EEGs are heavily corrupted by cardiac, eye movement, muscle, and noise artifacts and, as a consequence, some EEG features are irrelevant to classification problems. Combining the polynomial network and decision tree techniques, we discover comprehensible classification rules while also attempting to keep their classification error down. This technique is shown to out-perform a number of commonly used machine learning technique applied to automatically recognize artifacts in the sleep EEGs.

Schiff M, McKay MM. Urban youth disruptive behavioral difficulties: exploring association with parenting and gender. *Fam Process* 2003; 42(4):517-29. Abstract: The current study will examine behavioral difficulties among a sample of African American urban youth who were exposed to violence. Possible gender differences in disruptive behavioral difficulties, as well as possible associations between parental practices, family relationships, and youth disruptive behavioral difficulties are examined. A secondary data analysis from baseline data for 125 African American urban mothers and their children collected as part of a large-scale, urban, family-based, HIV prevention research study was analyzed. Findings reveal that externalizing behavioral problems in youth are associated with exposure to violence. Girls displayed significantly higher levels of externalizing behavioral difficulties than boys. Mothers' parenting practices and family relationships were associated with youths' externalizing behavior problems. Implications for interventions to reduce youths' exposure to violence and to develop gender sensitive interventions for youth and supportive interventions for their parents are discussed.

Schiller C, Allen PJ. Follow-up of infants prenatally exposed

to cocaine. *Pediatr Nurs* 2005; 31(5):427-36. Abstract: Maternal cocaine use during pregnancy continues to be of great concern for health care professionals. Research in this area has increased as investigators examine the effects of prenatal cocaine exposure in the infant/young child. This paper will critically review the literature, identify the primary care needs of infants and young children with a known history of prenatal cocaine exposure, and present guidelines for the primary care practitioner to monitor the infant's physiologic and developmental sequelae during the first 3 years of life. Findings in the literature demonstrate inconsistencies in regard to the physiologic and developmental outcomes of infants/young children prenatally exposed to cocaine. Further research is warranted, as it is evident from studies that not all investigators are controlling for confounding variables such as poly-drug use, which is necessary in isolating cocaine's effects. Subtle effects, however, have been reported from well-controlled studies and, thus, particular attention needs to be paid to early identification and interventions by primary care practitioners to prevent negative health outcomes. The guidelines proposed assist the practitioner with a thorough and focused approach to assessing the physiologic and developmental effects that are currently known to occur in the infant/young child prenatally exposed to cocaine.

Schlesinger LB. The contract murderer: patterns, characteristics, and dynamics. *J Forensic Sci* 2001; 46(5):1119-23.

Abstract: A case of an independent professional contract murderer, who killed over 100 people, is reported. After eluding law enforcement for 30 years, the subject killed several associates who he believed could implicate him in various crimes. These homicides eventually led to his arrest, since the victims were individuals who could be linked to him. This hit man had a background of poverty and childhood abuse but, as an adult, had pursued a middle-class lifestyle and kept his family totally separate from his criminal career. In addition, he had a number of characteristics that helped him carry out his crimes in a highly planned, methodical, and organized manner: he had adept social judgment; personality traits of orderliness, control, and paranoid vigilance; useful defense mechanisms of rationalization and reframing; and an exceptional ability to encapsulate emotions. This case is discussed within the context of contract murder, a crime that occurs relatively frequently and is probably increasing; yet it often goes undetected, the arrest rate is low, and the offender is rarely studied.

Schmahl CG, Elzinga BM, Vermetten E, Sanislow C, McGlashan TH, Bremner JD. Neural correlates of memories of abandonment in women with and without borderline personality disorder. *Biol Psychiatry* 2003; 54(2):142-51.

Abstract: BACKGROUND: Borderline personality

disorder (BPD) is a common psychiatric disorder that is often linked to early stressors. One particularly salient feature of the disorder is fear of abandonment. This pilot study was conducted to measure neural correlates of memories of abandonment in women with and without BPD. METHODS: Twenty women with a history of childhood sexual abuse underwent measurement of brain blood flow with positron emission tomography imaging while they listened to scripts describing neutral and personal abandonment events. Brain blood flow during exposure to abandonment and neutral scripts was compared among women with and without BPD. RESULTS: Memories of abandonment were associated with greater increases in blood flow in bilateral dorsolateral prefrontal cortex (middle frontal gyrus, Brodmann's areas 9 and 10) as well as right cuneus (area 19) in women with BPD than in women without BPD. Abandonment memories were associated with greater decreases in right anterior cingulate (areas 24 and 32) in women with BPD than in women without BPD. CONCLUSIONS: These findings implicate dysfunction of dorsolateral and medial prefrontal cortex including anterior cingulate, left temporal cortex, and visual association cortex in memories of abandonment in women with BPD. These brain areas may mediate symptoms of BPD.

Schmeck K, Poustka F. Temperament and disruptive behavior disorders. *Psychopathology* 2001; 34(3):159-63.

Abstract: In several studies on children with conduct disorder, difficult temperament in infancy was one of the major variables in the explanation of later aggressive behavior. According to these studies, subjects with a combination of high novelty seeking, low harm avoidance and low reward dependence (NS high, HA + RD low) should be most at risk for the development of disruptive behavior disorders. The Junior Temperament and Character Inventory was given to a clinical sample of 65 adolescent patients of both sexes with the diagnoses of conduct disorder (with and without attention deficit hyperactivity disorder), emotional disorder (anxiety disorder, obsessive-compulsive disorder, depressive disorder), eating disorder (anorexia, bulimia) or personality disorder (borderline and narcissistic personality disorder). High novelty seeking and low harm avoidance were significantly correlated with externalizing symptoms like aggression and delinquency. In conduct-disordered children and adolescents, we found significantly higher scores of NS compared to the other clinical groups and the normative population, and significantly lower scores of harm avoidance compared to the other clinical groups, but not compared to the normative population. The relative risk of having a conduct disorder was markedly higher in those children and adolescents with elevated scores of novelty seeking.

Schmidt C. Mothers' perceptions of self-care in school-age children with diabetes. *MCN Am J Matern Child Nurs*

2003; 28(6):362-70.  
Abstract: PURPOSE: To describe mothers' perceptions of the diabetes-related self-care abilities and practices of their school-age children with Type 1 diabetes. STUDY DESIGN AND METHOD: Qualitative study using the naturalistic inquiry method. Mothers of school-age children with diabetes were interviewed by means of a semi-structured interview guide. The children were between the ages of 11 and 12 and had been diagnosed with diabetes for a minimum of 2 years. Twelve mothers were interviewed, generating 20 hours of qualitative data. RESULTS: Mothers reported that their children with diabetes had learned skills in a predictable sequence, were usually motivated by events in the here and now, and did not consistently perform all diabetes-related skills of which they were capable. Most of the children were becoming embarrassed about having diabetes. There were considerable gender differences in the children's self-care development. CLINICAL IMPLICATIONS: Nurses can use this study to help with anticipatory guidance for parents. It may be helpful for parents to know the sequence in which many children learn diabetes-related skills, and to learn that even though a child is capable of task performance, he or she may not necessarily be ready for the independent practice or daily execution of the skill. Encouraging parents to stay involved with their children's self-care practices past the early adolescent years may be effective in improving self-care practices, and helping children to identify reasons to meet the self-care demands associated with diabetes can be beneficial.

Schmidt LS, Nielsen JE, Blichfeldt SS, Lund AM. [Metabolic disease or shaken baby syndrome?]. *Ugeskr Laeger* 2003; 165(35):3323-4. Abstract: We describe two children with subdural haematoma and glutaricacidaemia type 1, who were diagnosed late because of initial suspicion of shaken baby syndrome.

Schneider BA. Child welfare: court may determine whether life-sustaining treatment should be withdrawn. *J Law Med Ethics* 2003; 31(2):316-7.

Schneider JA. Janus-faced resilience in the analysis of a severely traumatized patient. *Psychoanal Rev* 2003; 90(6):869-87.

Schneider KM, Phares V. Coping with parental loss because of termination of parental rights. *Child Welfare* 2005; 84(6):819-42. Abstract: This article addresses the process by which children and adolescents cope with severe acute stress of parental loss from causes other than divorce or death. Participants were 60 children and adolescents from a residential treatment facility. Most had experienced neglect, physical abuse, and sexual abuse, and their parents had their parental rights terminated.

Measures of symptomatology indicated that children reported low levels of depressive symptoms, whereas caregivers reported the children were experiencing significant psychological problems. Children used avoidant coping strategies more often than emotion-focused coping strategies, which, in turn, were used more than problem-focused coping strategies. Results are discussed in terms of helping children cope with parental loss.

Schnitzer PG, Ewigman BG. Child injury deaths: comparing prevention information from two coding systems. *J Pediatr Psychol* 2005; 30(5):413-23. Abstract: OBJECTIVES: The International Classification of Disease (ICD) external cause of injury E-codes do not sufficiently identify injury circumstances amenable to prevention. The researchers developed an alternative classification system (B-codes) that incorporates behavioral and environmental factors, for use in childhood injury research, and compare the two coding systems in this paper. METHODS: All fatal injuries among children less than age five that occurred between January 1, 1992, and December 31, 1994, were classified using both B-codes and E-codes. RESULTS: E-codes identified the most common causes of injury death: homicide (24%), fires (21%), motor vehicle incidents (21%), drowning (10%), and suffocation (9%). The B-codes further revealed that homicides (51%) resulted from the child being shaken or struck by another person; many fires deaths (42%) resulted from children playing with matches or lighters; drownings (46%) usually occurred in natural bodies of water; and most suffocation deaths (68%) occurred in unsafe sleeping arrangements. CONCLUSIONS: B-codes identify additional information with specific relevance for prevention of childhood injuries.

Schoenhofer SO. Choosing personhood: intentionality and the theory of nursing as caring. *Holist Nurs Pract* 2002; 16(4):36-40. Abstract: Drawing on a story of a nursing situation for practical context, this article explores the meaning of intentionality within the theoretical context of Nursing as Caring. May's definition of intentionality as the structure that gives meaning to experience is interwoven with the concepts of the theory of Nursing as Caring to explore the topic. Mayeroff's concepts of hope and commitment contribute to an understanding of intentionality in relation to Nursing as Caring. The major thesis of this article, that intentionality is consistently choosing personhood as a way of life and the aim of nursing, is demonstrated in the practice situation.

Schoening AM, Greenwood JL, McNichols JA, Heermann JA, Agrawal S. Effect of an intimate partner violence educational program on the attitudes of nurses. *J Obstet Gynecol Neonatal Nurs* 2004; 33(5):572-9.

Abstract: **OBJECTIVE:** To examine the effect of an intimate partner violence (IPV) educational program on the attitudes of nurses toward victims. **DESIGN:** A quasi-experimental study utilizing a pretest and posttest. **SETTING:** An urban health care system. **PARTICIPANTS:** Fifty-two inpatient nurses completed both the pretest and posttest. **INTERVENTION:** One-hour and 3-hour IPV educational programs. **MAIN OUTCOME MEASURES:** Change in attitude was determined by scores from the Public Health Nurses' Response to Women Who Are Abused (PHNR), a standardized questionnaire that measures nurses' reactions to an IPV scenario. Parallel forms, each with a different scenario, were administered before and 2 months after the 1-hour and 3-hour educational sessions. Scores were analyzed using a repeated measures analysis of variance followed by multiple comparisons with Bonferroni adjustments. **RESULTS:** Nurses' PHNR scores increased significantly after attending the 1-hour session if they had previous IVP education and after the 3-hour session if they had no previous IVP education. **CONCLUSION:** Educational offerings should be tailored for nurses. For nurses with previous IVP education, offer a 1-hour update. For nurses with no previous IVP education, provide a 3-hour educational session. Further study is needed to determine if change in nurses' attitudes translates into improved screening, identification, and intervention for IPV victims.

Schoff EO, Hattenhauer MG, Ing HH *et al.* Estimated incidence of open-angle glaucoma in Olmsted County, Minnesota. *Ophthalmology* 2001; 108(5):882-6. Abstract: **PURPOSE:** To determine the incidence rates of open-angle glaucoma (OAG) in Olmsted County, MINNESOTA. **DESIGN:** Retrospective population-based estimate of incidence. **PARTICIPANTS:** From the medical histories of 60,666 residents of Olmsted County, Minnesota, who had ocular diagnoses during the study period, 114 subjects with newly diagnosed OAG were identified. **METHODS:** The database of the Rochester Epidemiology Project was used to identify all Olmsted County residents with a coded diagnosis of OAG, glaucoma suspect, or ocular hypertension during the period 1965 to 1980. Subjects newly diagnosed with and treated for OAG who also had documented clinical evidence of elevated intraocular pressure, optic nerve damage, and/or visual field loss consistent with glaucoma were included as incident cases. Population data for Olmsted County were drawn from United States Census data. Crude incidence data were adjusted to the age and gender distribution of the 1990 United States white population. **MAIN OUTCOME MEASURES:** Estimated incidence rates of OAG. **RESULTS:** The overall age- and gender-adjusted annual incidence rate of OAG in a predominantly Caucasian population is conservatively estimated to be 14.5 per 100,000 population. The rates increased with age from 1.6 in the fourth decade of life to 94.3 in the

eighth decade. There was no significant difference in incidence by gender. The average annual rate of OAG in the last 2 years of the study was 27.7 compared with 12.3 before 1979. This difference is suggestive of the effect of the introduction of a new medical therapy (timolol) for OAG during the last 2 years. **CONCLUSIONS:** The incidence rates of OAG increase markedly with advancing age, and screening efforts should be targeted at both men and women in the older age groups. The advent of new diagnostic and therapeutic modalities can have an effect on incidence rates.

Scholle SH, Gardner W, Harman J, Madlon-Kay DJ, Pascoe J, Kelleher K. Physician gender and psychosocial care for children: attitudes, practice characteristics, identification, and treatment. *Med Care* 2001; 39(1):26-38.

Abstract: **OBJECTIVE:** To examine differences by physician gender in the identification and treatment of childhood psychosocial problems. **DESIGN:** Survey of patients (n = 19,963) and physicians (n = 366) in primary care offices in 2 large, practice-based research networks. Multivariate regressions were used to control for patient, physician, and visit characteristics, with a correction for the clustered sample. **SUBJECTS:** Children ages 4 to 15 years seen consecutively for nonemergent care. **MEASURES:** Physician report of attitudes, training, practice factors, and identification and treatment of psychosocial problems. Parental report of demographics and behavioral symptoms. **RESULTS:** Compared with male physicians, female physicians were less likely to view care for psychosocial problems as burdensome. They were more likely to see children who were female, younger, black or Hispanic, in single-parent households, enrolled in public or managed health plans, and with physical health limitations. Children seen by male physicians had higher symptom counts. Male physicians were more likely to report having primary care responsibility for their patient and that parents agree with their care plan. Female physicians spent more time with patients. After controlling for these differences, female physicians did not differ from male physicians in identification or treatment of childhood psychosocial problems. **CONCLUSIONS:** Male and female physicians see different kinds of children for different visit purposes and have different kinds of relationships with their patients. After controlling for these factors, management of childhood psychosocial problems does not differ by physician gender. Improving management of psychosocial conditions depends on identifying modifiable factors that affect diagnosis and treatment; our work suggests that characteristics of the practice environment, physician-patient relationship, and patient self-selection deserve more research.

discussion 963-8.

Schor EL. Family pediatrics: report of the Task Force on the Family. *Pediatrics* 2003; 111(6 Pt 2):1541-71. Notes: CORPORATE NAME: American Academy of Pediatrics Task Force on the Family Abstract: WHY A TASK FORCE ON THE FAMILY? The practice of pediatrics is unique among medical specialties in many ways, among which is the nearly certain presence of a parent when health care services are provided for the patient. Regardless of whether parents or other family members are physically present, their influence is pervasive. Families are the most central and enduring influence in children's lives. Parents are also central in pediatric care. The health and well-being of children are inextricably linked to their parents' physical, emotional and social health, social circumstances, and child-rearing practices. The rising incidence of behavior problems among children attests to some families' inability to cope with the increasing stresses they are experiencing and their need for assistance. When a family's distress finds its voice in a child's symptoms, pediatricians are often parents' first source for help. There is enormous diversity among families-diversity in the composition of families, in their ethnic and racial heritage, in their religious and spiritual orientation, in how they communicate, in the time they spend together, in their commitment to individual family members, in their connections to their community, in their experiences, and in their ability to adapt to stress. Within families, individuals are different from one another as well. Pediatricians are especially sensitive to differences among children-in their temperaments and personalities, in their innate and learned abilities, and in how they view themselves and respond to the world around them. It is remarkable and a testament to the effort of parents and to the resilience of children that most families function well and most children succeed in life. Family life in the United States has been subjected to extensive scrutiny and frequent commentary, yet even when those activities have been informed by research, they tend to be influenced by personal experience within families and by individual and cultural beliefs about how society and family life ought to be. The process of formulating recommendations for pediatric practice, public policy, professional education, and research requires reaching consensus on some core values and principles about family life and family functioning as they affect children, knowing that some philosophic disagreements will remain unresolved. The growing multicultural character of the country will likely heighten awareness of our diversity. Many characteristics of families have changed during the past 3 to 5 decades. Families without children younger than 18 years have increased substantially, and they are now the majority. The average age at marriage has increased, and a greater proportion of births is occurring to women older than 30 years. Between 1970 and 2000, the proportion of

children in 2-parent families decreased from 85% to 69%, and more than one quarter (26%) of all children live with a single parent, usually their mother. Most of this change reflects a dramatic increase in the rate of births to unmarried women that went from 5.3% in 1960 to 33.2% in 2000. Another factor in this change is a slowly decreasing but still high divorce rate that is roughly double what it was in the mid-1950s. Family income is strongly related to children's health, and the financial resources that families have available are closely tied to changes in family structure. Family income in real dollars has trended up for many decades, but the benefits have not been shared equally. For example, the median income of families with married parents has increased by 146% since 1970, but female-headed households have experienced a growth of 131%. More striking is that in 2000, the median income of female-headed households was only 47% of that of married-couple families and only 65% of that of families with 2 married parents in which the wife was not employed. Not surprising, the proportion of children who live in poverty is approximately 5 times greater for female-headed families than for married-couple families. The comped families than for married-couple families. The composition of children's families and the time parents have for their children affect child rearing. Consequent to the increase in female-headed households, rising economic and personal need, and increased opportunities for women, the proportion of mothers who are in the workforce has climbed steadily over the past several decades. Currently, approximately two thirds of all mothers with children younger than 18 years are employed. Most families with young children depend on child care, and most child care is not of good quality. Reliance on child care involves longer days for children and families, the stress imposed by schedules and created by transitions, exposure to infections, and considerable cost. An increasing number and proportion of parents are also devoting time previously available to their children to the care of their own parents. The so-called "sandwich generation" of parents is being pulled in multiple directions. The amount and use of family time also has changed with a lengthening workday, including the amount of commuting time necessary to travel between work and home, and with the intrusion of television and computers into family life. In public opinion polls, most parents report that they believe it is more difficult to be a parent now than it used to be; people seem to feel more isolated, social and media pressures on and enticements of their children seem greater, and the world seems to be a more dangerous place. Social and public policy has not kept up with these changes, leaving families stretched for time and stressed to cope and meet their responsibilities. What can and what should pediatrics do to help families raise healthy and well-adjusted children? How can individual pediatricians better support families? FAMILY PEDIATRICS: The American Academy of Pediatrics (AAP) Board of Directors appointed the Task Force on

the Family to help guide the development of public policy and recommend how to assist pediatricians to promote well-functioning families (see Appendix). The magnitude of the assigned work required task force members to learn a great deal from research and researchers in the fields of social and behavioral sciences. A review of some critical literature was completed by a consultant to the task force and accompanies this report. That review identified a convergence of pediatrics and research on families by other disciplines. The task force found that a great deal is known about family functioning and family circumstances that affect children. With this knowledge, it is possible to provide pediatric care in a way that promotes successful families and good outcomes for children. The task force refers to that type of care as "family-oriented care" or "family pediatrics" and strongly endorses policies and practices that promote the adoption of this 2-generational approach as a hallmark of pediatrics. During the past decade, family advocates have successfully promoted family-centered care, "the philosophies, principles and practices that put the family at the heart or center of services; the family as the driving force." Most pediatricians report that they involve families in the decision making regarding the health care of their child and make an effort to understand the needs of the family as well as the child. Family pediatrics, like family-centered care, requires an active, productive partnership between the pediatrician and the family. But family pediatrics extends the responsibilities of the pediatrician to include screening, assessment, and referral of parents for physical, emotional, or social problems or health risk behaviors that can adversely affect the health and emotional or social well-being of their child.

**FAMILY CONTEXT OF CHILD HEALTH:** The power and importance of families to children arises out of the extended duration for which children are dependent on adults to meet their basic needs. Children's needs for which only a family can provide include social support, socialization, and coping and life skills. Their self-esteem grows from being cared for, loved, and valued and feeling that they are part of a social unit that shares values, communicates openly, and provides companionship. Families transmit and interpret values to their children and often serve as children's connection to the larger world, especially during the early years of life. Although schools provide formal education, families teach children how to get along in the world. Often, efforts to discuss families and make recommendations regarding practice or policy stumble over disagreements about the definition of a family. The task force recognized the diversity of families and chose not to operate from the position of a fixed definition. Rather, the task force, which was to address pediatrics, decided to frame its deliberations and recommendations around the functions of families and how various aspects of the family context influence child rearing and child health. One model of family

functioning that implicitly guided the task force is the family stress model (Fig 1). Stress of various sorts (eg, financial or health problems, lack of social support, unhappiness at work, unfortunate life events) can cause parents emotional distress and cause couples conflict and difficulty with their relationship. These responses to stress then disrupt parenting and the interactions between parent and child and can lead to short-term or lasting poor outcomes. The earlier these events transpire and the longer that the disruption lasts, the worse the outcomes for children. The task force favors efforts to encourage and support marriage yet recognizes that every family constellation can produce good outcomes for children and that none is certain to yield bad ones. Schreier HA, Ayoub CC. Casebook companion to the definitional issues in Munchausen by proxy position paper. *Child Maltreat* 2002; 7(2):160-5.

Schuiling GA. Honor your father and your mother. *J Psychosom Obstet Gynaecol* 2001; 22(4):215-9. Abstract: While on the one hand there is much mutual love and care in the relationship between parents and their offspring, there may, on the other hand, be also much mutual 'sound and fury', which sometimes is far from 'signifying nothing' (William Shakespeare, *Macbeth*). Indeed, from conception on, individuals are confronted with parent-offspring conflicts of all kinds. Initially these conflicts concern physiological matters (implantation, nutrition, weaning, etc.), but later in life the accent is on psychological ('you must this', 'you must that', 'don't do that' etc.) and social affairs, and phenomena such as child abuse, infanticide and incest may occur. It is, therefore, certainly not self-evident that children honor their parents. To reinforce their position, parents (societies) may appeal to a 'divine' commandment which helps them make their children suppress any tendency to conflict toward them (and hence to their culture), so that children conform to their parents' norms and values. When such psychological and sociological parent-offspring conflicts are not resolved satisfactorily, it can be suggested, children may (consciously or unconsciously) have aggressive feelings toward their parents: Freud's 'Oedipus complex'. This complex, it is argued, can also be seen as a parent-offspring conflict. Given their biological basis, parent-offspring conflicts can hardly be considered as abnormal. Conflicts between adults and their offspring have always existed and will always exist, simply because it is inherent in our genetic make-up: parents and offspring of sexually reproducing species--humans included--are only about 50% genetically related and hence have different interests at all levels of being. Indeed, parent-offspring conflicts are such stuff as we are made on, and our little life is

rounded with its consequences (adapted from William Shakespeare, *The Tempest*).

Schuler ME, Nair P. Witnessing violence among inner-city children of substance-abusing and non-substance-abusing women. *Arch Pediatr Adolesc Med* 2001; 155(3):342-6.

Abstract: OBJECTIVES: To determine if children of substance-abusing mothers witness more violence than children of non-substance-abusing (control) mothers, and to determine if children who witness violence have more behavioral problems and higher stress scores than children who do not witness violence. DESIGN: Cross-sectional research design comparing exposure to violence among children of substance-abusing mothers and control mothers of low socioeconomic status. SETTING: An inner-city pediatric clinic. PARTICIPANTS: Forty substance-abusing mothers and their children, and 40 non-substance-abusing mothers and their children, examined when the children were 6 years old. MAIN OUTCOME MEASURES: Maternal report of children's exposure to violence was assessed using the Exposure to Violence Interview and the Conflict Tactics Scale. Maternal report of children's behavior was assessed using the Child Behavior Checklist and the Children's Response to Stress Inventory. RESULTS: Children of substance-abusing mothers did not witness more violence than the control children ( $P > .05$ ). However, 6-year-old inner-city children in the present study witnessed a high rate of violence: 43% had seen someone beaten up, 13% had seen someone threatened with a knife, and 7% had seen someone stabbed or shot. Children witnessing violence had significantly higher aggressive, delinquent, anxious/depressed, withdrawn, attention, and social problems ( $P < .05$ ) on the Child Behavior Checklist, and higher stress scores ( $P = .05$ ) on the Children's Response to Stress Inventory. CONCLUSIONS: More than half of the 6-year-old inner-city children in the present study witnessed some form of violence. Witnessing violence was associated with more behavioral problems and higher stress scores as assessed through maternal report. Subsequent research should examine the long-term effects of this exposure to violence among young children.

Schuler ME, Nair P, Kettinger L. Drug-exposed infants and developmental outcome: effects of a home intervention and ongoing maternal drug use. *Arch Pediatr Adolesc Med* 2003; 157(2):133-8. Abstract: OBJECTIVE: To evaluate the effects of a home intervention and ongoing maternal drug use on the developmental outcome of drug-exposed infants. DESIGN: Longitudinal randomized cohort study of a home intervention with substance-abusing mothers and their infants. Mother-infant dyads were randomly assigned to a control or intervention group at 2 weeks' post partum. Control families received brief monthly tracking visits. Intervention families received weekly home visits from 0 to 6 months and biweekly visits

from 6 to 18 months by trained lay visitors. PARTICIPANTS: One hundred eight low-income, inner-city, drug-exposed children (control, 54; intervention, 54) who underwent developmental testing at 6, 12, and 18 months post partum and who remained with their biological mothers through 18 months. MAIN OUTCOME MEASURES: Infant scores from the Bayley Scales of Infant Development (BSID) at 6, 12, and 18 months post partum. Maternal report of drug use during the pregnancy and ongoing drug use through 18 months post partum was assessed. RESULTS: In the repeated-measures analyses, intervention infants had significantly higher BSID Mental Developmental Index (MDI) and Psychomotor Developmental Index scores than control infants. Ongoing maternal cocaine and/or heroin use was associated with lower MDI scores. Finally, MDI scores decreased significantly in both groups. CONCLUSIONS: Ongoing maternal drug use is associated with worse developmental outcomes among a group of drug-exposed infants. A home intervention led to higher BSID scores among drug-exposed infants. However, BSID MDI scores decreased during the first 18 months post partum among inner-city, low-socioeconomic-status infants in the present study.

Schulting AB, Malone PS, Dodge KA. The effect of school-based kindergarten transition policies and practices on child academic outcomes. *Dev Psychol* 2005; 41(6):860-71.

Abstract: This study examined the effect of school-based kindergarten transition policies and practices on child outcomes. The authors followed 17,212 children from 992 schools in the Early Childhood Longitudinal Study-Kindergarten sample (ECLS-K) across the kindergarten school year. Hierarchical linear modeling revealed that the number of school-based transition practices in the fall of kindergarten was associated with more positive academic achievement scores at the end of kindergarten, even controlling for family socioeconomic status (SES) and other demographic factors. This effect was stronger for low- and middle-SES children than high-SES children. For low-SES children, 7 transition practices were associated with a .21 standard deviation increase in predicted achievement scores beyond 0 practices. The effect of transition practices was partially mediated by an intervening effect on parent-initiated involvement in school during the kindergarten year. The findings support education policies to target kindergarten transition efforts to increase parent involvement in low-SES families.

Schultz ST, Shenkin JD, Horowitz AM. Parental perceptions of unmet dental need and cost barriers to care for developmentally disabled children. *Pediatr Dent* 2001; 23(4):321-5.

Abstract: PURPOSE: The purpose of this investigation was to describe and assess the disparities, if any, in parental perceived cost barriers to oral health care

among developmentally disabled children using a national data set. **METHODS:** Data from the 1997 National Health Interview Survey (NHIS) were analyzed using a SUDAAN statistical package. **RESULTS:** After adjusting for age and sex, parental perception of unmet need was significantly associated with developmentally disabled children 2-17 years in lower socioeconomic groups. **CONCLUSIONS:** Though most children from lower socioeconomic groups are eligible for Medicaid coverage, parents of these children perceive cost barriers to dental care. Children with developmental disabilities face even more perceived barriers to care based on family income.

Schutte AR, Spencer JP, Schonher G. Testing the dynamic field theory: working memory for locations becomes more spatially precise over development. *Child Dev* 2003; 74(5):1393-417.

**Abstract:** The dynamic field theory predicts that biases toward remembered locations depend on the separation between targets, and the spatial precision of interactions in working memory that become enhanced over development. This was tested by varying the separation between A and B locations in a sandbox. Children searched for an object 6 times at an A location, followed by 3 trials at a B location. Two- and 4-year-olds', but not 6-year-olds', responses were biased toward A when A and B were 9-in. and 6-in. apart. When A and B were separated by 2 in., however, 4- and 6-year-olds' responses were biased toward A. Thus, the separation at which responses were biased toward A decreased across age groups, supporting the predictions of the theory.

Schutzer SE, Budowle B, Atlas RM. Biocrimes, microbial forensics, and the physician. *PLoS Med* 2005; 2(12):e337.

Scott C. Who is responsible for child protection? *Prof Nurse* 2003; 18(5):242.

Scott CL, Gerbasi JB. Sex offender registration and community notification challenges: the Supreme Court continues its trend. *J Am Acad Psychiatry Law* 2003; 31(4):494-501.

**Abstract:** All states and the District of Columbia have passed sex offender registration and community notification laws. While the specific provisions of these statutes vary, all have public safety as a primary goal. The authors discuss two recent cases heard by the United States Supreme Court that challenged the constitutionality of Alaska's and Connecticut's statutes. The laws were challenged as violations of the United States Constitution's prohibition on ex post facto laws and its Fourteenth Amendment guarantee of procedural due process. In both cases, the statutes were upheld. As it has found in challenges to sexually violent predator statutes, the Court emphasized that the registration and

community notification schemes are civil and not criminal in nature. The article concludes with a discussion of possible implications for clinicians involved in evaluating or treating sex offenders.

Scott D. A promise unfulfilled on child abuse. *Aust N Z J Public Health* 2002; 26(5):415-6.

Scott D, Brady S, Glynn P. New mother groups as a social network intervention: consumer and maternal and child health nurse perspectives. *Aust J Adv Nurs* 2001; 18(4):23-9.

**Abstract:** Maternal and child health nurses in two outer urban local government areas in Melbourne, Australia were interviewed about how they facilitated first-time parent groups. Groups were offered to all first time mothers and almost two thirds of mothers joined a group. The groups ran for approximately eight sessions and provided infant-focussed parent education and social contact. Women who joined the groups were followed up 18 months to two years later to determine the degree to which these groups continued to meet on their own accord and the extent to which they had become self-sustaining social networks. The study found a very high level of continuation, suggesting that providing such programs may be an important vehicle for enhancing social support during the transition to parenthood and thus be a useful primary prevention strategy.

Scourfield J, Van den Bree M, Martin N, McGuffin P. Conduct problems in children and adolescents: a twin study. *Arch Gen Psychiatry* 2004; 61(5):489-96.

**Abstract:** **BACKGROUND:** Evidence supports a genetic influence on conduct problems as a continuous measure of behavior and as a diagnostic category. However, there is a lack of studies using a genetically informative design combined with several different informants and different settings. **OBJECTIVES:** To examine genetic and environmental influences on conduct problems rated by parent and teacher reports and self-reports and to determine whether their ratings reflect a common underlying phenotype. **DESIGN:** A twin study design was used to examine conduct problem scores from ratings by teachers, parents, and twins themselves. **SETTING:** General community. **PARTICIPANTS:** Twins aged 5 to 17 years participating in the Cardiff Study of All Wales and North England Twins (CaStANET) project. **MAIN OUTCOME MEASURES:** Conduct problem scale from the Strengths and Difficulties Questionnaire. **RESULTS:** Conduct problem scores were significantly heritable based on parent and teacher reports and self-reports. Combining data from all 3 informants showed that they are rating a common underlying phenotype of pervasive conduct problems that is entirely genetic, while teacher ratings show separate genetic influences that are not shared with other raters. **CONCLUSIONS:** Conduct problems are significantly heritable based on

parent and teacher reports and self-reports, and are also influenced by environmental effects that impinge uniquely on children from the same family. There is a cross-situational conduct problems' phenotype, underlying the behavior measured by all informants, that is wholly genetic in origin. No significant influence of shared environmental effects was found.

Seals D, Young J. Bullying and victimization: prevalence and relationship to gender, grade level, ethnicity, self-esteem, and depression. *Adolescence* 2003; 38(152):735-47.

Abstract: This study investigated the prevalence of bullying and victimization among students in grades 7 and 8. It also explored the relationship of bullying and victimization to gender, grade level, ethnicity, self-esteem, and depression. Three survey instruments were used to obtain data from a convenience sample of 454 public school students. Twenty-four percent reported bullying involvement. Chi-square tests indicated significantly more male than female bullying involvement, seventh graders reported more involvement than did eighth graders, and there were no statistically significant differences in involvement based on ethnicity. Both bullies and victims manifested higher levels of depression than did students who were neither bullies nor victims. There were no significant differences between groups in terms of self-esteem.

Sears ES, Anthony JC. Artificial neural networks for adolescent marijuana use and clinical features of marijuana dependence. *Subst Use Misuse* 2004; 39(1):107-34.

Abstract: This article compares the performance of multiple logistic regression (MLR) with feed-forward, artificial neural network (ANN) models for the assessment of adolescent marijuana use and clinical features of dependence based on self-evaluation from recent National Household Surveys on Drug Abuse (NHSDA). The effect of training and testing the neural networks with randomly selected data was compared to data selected as a function of survey year. The technical aim of the study was to account for adolescent marijuana use and features of marijuana dependence based on experiences with alcohol and tobacco. Similarities observed in MLR and ANN model performance may indicate no major complex or nonlinear relationships in cross-sectional epidemiological data selected to model adolescent drug use and dependence in this specific application. We concluded that ANNs should be further studied in future longitudinal research, perhaps with modeling of recursive networks, allowing feedback from drug dependence to levels of marijuana use. The ANN models also have the potential to model drug use and dependence based on input parameters with no obvious direct link to drug involvement--e.g., polymorphisms associated with "openness to experience" or other personality traits hypothesized to function as distal antecedents, and could thus be implemented to identify

higher risk youths using assessments indirectly related or nonlinearly associated to adolescent drug use and dependence but less sensitive to survey-related response tendencies.

Sebre S, Sprugevica I, Novotni A *et al.* Cross-cultural comparisons of child-reported emotional and physical abuse: rates, risk factors and psychosocial symptoms. *Child Abuse Negl* 2004; 28(1):113-27. Abstract: OBJECTIVES: This study was designed to assess the incidence of child emotional and physical abuse, associated risk factors and psychosocial symptoms in a cross-cultural comparison between post-communist bloc countries. Method: One-thousand one-hundred forty-five children ages 10-14 from Latvia (N = 297), Lithuania (N = 300), Macedonia (N = 302), and Moldova (N = 246) participated in the study. They completed questionnaires assessing their experience of emotional or physical abuse, and provided information about family risk-factors and psychosocial symptoms, including PTSD-related symptoms. RESULTS: Incidence rates of maltreatment differed by country, as did levels of reported psychosocial symptoms. Incidence of emotional and physical abuse differed by region, with higher levels of abuse reported in the rural regions. In all four countries, a similar association between emotional/physical abuse and psychosocial symptoms was found, with the uniformly largest correlation between emotional abuse and anger. When examining the combined scores of emotional and physical abuse, even higher correlations were found, particularly in relation to anger and depression. In all four countries, parental overuse of alcohol was associated with emotional and/or physical abuse. CONCLUSIONS: Findings show differences by country in child-reported levels of emotional and physical abuse, but similar patterns of correlation with psychosocial symptoms and the risk factors of parental alcohol overuse and living in a rural area.

Seidman LJ, Valera EM, Makris N. Structural brain imaging of attention-deficit/hyperactivity disorder. *Biol Psychiatry* 2005; 57(11):1263-72. Abstract: Many investigators have hypothesized that attention-deficit/hyperactivity disorder (ADHD) involves structural and functional brain abnormalities in frontal-striatal circuitry. Although our review suggests that there is substantial support for this hypothesis, a growing literature demonstrates widespread abnormalities affecting other cortical regions and the cerebellum. Because there is only one report studying adults with ADHD, this summary is based on children. A key limitation of the literature is that most of the studies until recently have been underpowered, using samples of fewer than 20 subjects per group. Nevertheless, these studies are largely consistent with the most comprehensive and definitive study (Castellanos *et al* 2002). Moreover, studies differ in the degree to which they address the influence of medications, comorbidities, or gender, and most have

not addressed potentially important sources of heterogeneity such as family history of ADHD, subtype, or perinatal complications. Despite these limitations, a relatively consistent picture has emerged. The most replicated alterations in ADHD in childhood include significantly smaller volumes in the dorsolateral prefrontal cortex, caudate, pallidum, corpus callosum, and cerebellum. These results suggest that the brain is altered in a more widespread manner than has been previously hypothesized. Developmental studies are needed to address the evolution of this brain disorder into adulthood.

Seifer R, LaGasse LL, Lester B *et al.* Attachment status in children prenatally exposed to cocaine and other substances. *Child Dev* 2004; 75(3):850-68. Abstract: Attachment status of children exposed in utero to cocaine, opiates, and other substances was examined at 18 months (n=860) and 36 months (n=732) corrected age. Children exposed to cocaine and opiates had slightly lower rates of attachment security (but not disorganization), and their insecurity was skewed toward ambivalent, rather than avoidant, strategies. Continued postnatal alcohol use was associated with higher rates of insecurity and disorganization at 18, but not 36, months of age. Stability of attachment across the 18-month period was barely above chance expectation. Attachment status at 18 months was associated with child temperament and caregiver-child interaction; at 36 months, attachment was associated with child temperament, child behavior problems, and caregivers' parenting self-esteem.

Seipp CM, Johnston C. Mother-son interactions in families of boys with Attention-Deficit/Hyperactivity Disorder with and without oppositional behavior. *J Abnorm Child Psychol* 2005; 33(1):87-98. Abstract: Parenting responsiveness and over-reactivity were assessed among 25 mothers of 7-9-year-old sons with Attention-Deficit/Hyperactivity Disorder (ADHD) and oppositional behavior (Oppositional Defiant, OD), 24 mothers of sons with ADHD only, and 38 mothers of nonproblem sons. Responsiveness was observed during mother-son play and clean-up interactions and over-reactivity was assessed using self-reports of parenting in discipline situations. Mothers of sons with ADHD/OD were less responsive and more over-reactive than mothers of nonproblem sons, and mothers of sons with ADHD only did not differ from the other groups. Mothers of sons with ADHD/OD reported more hostility than mothers of nonproblem sons, and controlling for maternal hostility eliminated the significant group differences in responsiveness during clean-up and in over-reactivity. Controlling for the child's ADHD subtype did not alter the pattern of results. The implications for addressing responsiveness and over-reactivity as components of parent-mediated behavioral treatments for ADHD are considered.

Seker H, Evans DH, Aydin N, Yazgan E. Compensatory fuzzy neural networks-based intelligent detection of abnormal neonatal cerebral Doppler ultrasound waveforms. *IEEE Trans Inf Technol Biomed* 2001; 5(3):187-94.

Abstract: Compensatory fuzzy neural networks (CFNN) without normalization, which can be trained with a backpropagation learning algorithm, is proposed as a pattern recognition technique for intelligent detection of Doppler ultrasound waveforms of abnormal neonatal cerebral hemodynamics. Doppler ultrasound signals were recorded from the anterior cerebral arteries of 40 normal full-term babies and 14 mature babies with intracranial pathology. The features of normal and abnormal groups as inputs to pattern recognition algorithms were extracted from the maximum velocity waveforms by using principal component analysis. The proposed technique is compared with the CFNN with normalization and other pattern recognition techniques applied to Doppler ultrasound signals from various arteries. The results show that the proposed method is superior to the others, and can be a powerful technique to be used in analyzing Doppler ultrasound signals from various arteries.

Sekhobo JP, Druschel CM. An evaluation of congenital malformations surveillance in New York State: an application of Centers for Disease Control and Prevention (CDC) guidelines for evaluating surveillance systems. *Public Health Rep* 2001; 116(4):296-305.

Abstract: Established in 1982, the New York State Congenital Malformations Registry (NYCMR) is one of the largest statewide, population-based birth defects registries in the nation. In this article, we evaluate the surveillance of congenital malformations in New York State using the Centers for Disease Control and Prevention (CDC) guidelines for evaluating public health surveillance systems. In addition to the evaluation of selected qualitative and quantitative system attributes, we assess the public health significance and usefulness of the surveillance system and how well it is meeting its stated objectives. The NYCMR uses passive case ascertainment, relying on reports from hospitals and physicians. A congenital malformation is defined as any structural, functional, or biochemical abnormality determined genetically or induced during gestation and not due to birthing events. In addition to being the primary source of congenital malformations surveillance data in New York State, the NYCMR also provides cases for traditional epidemiological studies to determine risk factors for specific congenital malformations. The NYCMR has been working to meet its stated objectives while striving to improve its qualitative and quantitative

attributes. Registry personnel have implemented several measures designed to enhance the simplicity of the data collection and data entry processes, as well as to maintain the acceptability of the surveillance system to the reporting sources. Because it is a statewide, population-based surveillance system, by far the strongest quantitative attribute of the NYCMR is representativeness. The sensitivity of the NYCMR is difficult to evaluate. Available estimates suggest, however, that the NYCMR identifies a large proportion of children born with congenital malformations in New York State and diagnosed from birth through two years of life. Finally, the NYCMR has in recent years been able to publish and disseminate annual reports describing the distribution of specific malformations in New York State on a timely basis.

Selbst SM. Pediatric emergency medicine: legal briefs. *Pediatr Emerg Care* 2004; 20(11):786-90.

Selinske J, Naughton D, Flanagan K, Fry P, Pickles A. Ensuring the best interest of the child in intercountry adoption practice: case studies from the United Kingdom and the United States. *Child Welfare* 2001; 80(5):656-67.

Abstract: Each year, thousands of children who cross international borders are destined for homes with adoptive families. For most, this journey from their homeland brings them to loving new homes where they will thrive and prosper. For others, the journey is hazardous and the destination uncertain.

Seltzer AG, Vilke GM, Chan TC, Fisher R, Dunford JV. Outcome study of minors after parental refusal of paramedic transport. *Prehosp Emerg Care* 2001; 5(3):278-83.

Abstract: **OBJECTIVE:** Patient refusal of paramedic transport against medical advice (AMA) has significant medical-legal implications. Previous studies have investigated patient outcomes after refusal of transport, but none has focused on these events in minors. This study was performed to evaluate the outcomes of this patient population after refusal of transport as well as the significance of base hospital physician discussion with parents in the decision to refuse transport. **METHODS:** This was a retrospective telephone follow-up survey involving parents of minors for whom transport was refused after accessing emergency medical services (EMS) via the 911 system. Data were initially obtained from paramedic run records and each family was subsequently contacted by telephone and surveyed with regard to their experiences with the field medics in addition to the medical follow-up sought for their child and patient outcomes. **RESULTS:** Eighty-nine patients met criteria for survey. Telephone contact was made with 44 parents, of whom 32 (73% of those contacted, 36% overall) participated. Twenty-seven (84%) received medical follow-up, either at an emergency department or in a private physician's

office. Most patients (89%) who were evaluated and/or treated by a physician were subsequently released, while three children were admitted to the hospital, all three with respiratory or cardiac chief complaints. **CONCLUSIONS:** Children whose parents refused EMS transport received medical follow-up in the majority of cases, with a small group requiring admission.

Semansky RM, Koyanagi C, Vandivort-Warren R. Behavioral health screening policies in Medicaid programs nationwide. *Psychiatr Serv* 2003; 54(5):736-9.

Abstract: Under the Early and Periodic Screening, Diagnosis, and Treatment (EPSDT) mandate, states are required to screen Medicaid-insured children for mental health and substance use disorders. This national study found that states vary considerably in their policies. Nearly half the states (23 in total) have not addressed behavioral health issues in their EPSDT screening tools at all. More states have screening tools that address mental health than substance use disorders. Most states have created their own screening tools, which suggests discomfort with or a lack of awareness of the standard tools available. Screening policy options to increase behavioral health screening rates are discussed.

Senn CY, Desmarais S. Impact of interaction with a partner or friend on the exposure effects of pornography and erotica. *Violence Vict* 2004; 19(6):645-58.

Abstract: Past studies on the effects of sexually explicit materials on women have tended to study them alone, in pairs, or in groups of strangers. By contrast, our study randomly assigned women to bring either a same-sex friend or a male partner to reflect more natural viewing conditions. Discussion between the participant and her companion followed exposure to the sexual images. Women who viewed pornography maintained their (quite high) level of negative mood, whereas women who viewed erotica experienced a substantial improvement in mood. The sex of the companion did not have a direct influence on participants' mood, with discussion improving mood across the board. However, participants' ratings of their satisfaction with the discussion were significantly influenced by the sex of their companion. We suggest that future research should focus more on the interpersonal aspects of male-female relationships when exploring the effects of sexually explicit materials on heterosexual women.

Sera MD, Elieff C, Forbes J, Burch MC, Rodriguez W, Dubois DP. When language affects cognition and when it does not: an analysis of grammatical gender and classification. *J Exp Psychol Gen* 2002; 131(3):377-97.

Abstract: The focus of this work was on the relation between grammatical gender and categorization. In one set of studies, monolingual English-, Spanish-, French-,

and German-speaking children and adults assigned male and female voices to inanimate objects. Results from Spanish and French speakers indicated effects of grammatical gender on classification; results from German speakers did not. A connectionist model simulated the contradicting findings. The connectionist networks were also used to investigate which aspect of grammatical gender was responsible for the different pattern of findings. The predictions from the connectionist simulations were supported by the results from an artificial language-learning task. The results from this work demonstrate how connectionist networks can be used to identify the differences between languages that affect categorization.

Sergi C, Linderkamp O. Pathological case of the month: classic rickets in a setting of significant psychosocial deprivation. *Arch Pediatr Adolesc Med* 2001; 155(8):967-8.

Serhatlioglu S, Hardalac F, Guler I. Classification of transcranial Doppler signals using artificial neural network. *J Med Syst* 2003; 27(2):205-14. Abstract: Transcranial Doppler signals, recorded from the temporal region of brain on 110 patients were transferred to a personal computer by using a 16-bit sound card. The fast Fourier transform (FFT) method was applied to the recorded signal from each patient. Since FFT method inherently can not offer a good spectral resolution at jet blood flows, it sometimes causes wrong interpretation of transcranial Doppler signals. To do a correct and rapid diagnosis, transcranial Doppler blood flow signals were statistically arranged so that they were classified in artificial neural network. Back propagation neural network and self-organization map algorithms of artificial neural network were used for training, whereas momentum and delta-bar-delta algorithms were used for learning. The results of these algorithms were compared in the case of classification and learning.

Serrano-Durba A, Serrano AJ, Magdalena JR *et al.* The use of neural networks for predicting the result of endoscopic treatment for vesico-ureteric reflux. *BJU Int* 2004; 94(1):120-2. Abstract: OBJECTIVE: To create an artificial neural network (ANN) to aid in predicting the results of endoscopic treatment for vesico-ureteric reflux (VUR). MATERIALS AND METHODS: During 1999-2001 we used endoscopic treatment in 261 ureteric units with VUR of all grades and causes. An ANN based on multilayer perceptron architecture was created using an 11 x 6 x 1 structure, taking the following as variables: the cause and grade of VUR, the patient's age and sex, the type of implanted substance and its volume, the number of treatments, the affected ureter, the endoscopic findings, and the type of cystography used. In all, 174 cases were used as training samples for the

ANN and 87 to validate it. We calculated the sensitivity, specificity, positive (PPV) and negative predictive values (NPV), and the success rate (%) of the system. RESULTS: In the training group the ANN gave a sensitivity of 86.4%, a specificity of 89.5%, a PPV of 76% and NPV of 94%, with a success rate of 88.6%. In the same training group logistic regression (LR) gave respective values of 68.2%, 58.8%, 39%, 82.7% and 61.4%. In the validation group the respective values for the ANN were 71.4%, 81.6%, 58.8%, 88.6% and 78.9%, and in the same validation group the LR gave 64.4%, 50%, 32.1%, 79.2% and 53.9%. The Wilcoxon test confirmed the independence of both methods ( $P < 0.001$ ). CONCLUSION: The ANN is an effective tool for assisting the urologist in indicating and applying endoscopic treatments for VUR.

Sevecke K, Krischer MK, Schonberg T, Lehmkuhl G. [The psychopathy-concept and its psychometric evaluation in childhood and adolescence]. *Prax Kinderpsychol Kinderpsychiatr* 2005; 54(3):173-90. Abstract: In accordance with Robert Hare's concept, over twenty years the word psychopathy is used to describe a specific combination of affective and interpersonal traits in adults as subtype of antisocial personality disorder. Recently in North America personality traits of psychopathy have also been studied in juveniles (and children). The Psychopathy Checklist: Youth Version (PCL-YV) was developed to take the special conditions of adolescents into account and focuses on assessing personality dimensions from age 12 upwards. In juveniles with a high score, research with the PCL-YV demonstrated for example a lack of empathy, impulsivity and social adjustment disorder. Furthermore, researchers found associations between the number and severity of violent offences, early drug abuse and heightened recidivism. This paper discusses the concept of psychopathy for adolescents on the basis of 3 case reports. Biological determinants, experimental results and diagnostic aspects are described.

Shaham R. Revealing the secrets of the body: medical tests as legal evidence in personal status disputes in modern Egypt. *Med Law* 2003; 22(1):131-54. Abstract: The study seeks to answer the following question: In the field of personal status, what kinds of medical tests have been considered reliable and acceptable by Egyptian courts of law, what kinds have been less accepted, and why? The main finding is that,

on the one hand, the judges (qadis) have welcomed tests that seek to determine age or to discover physical diseases and/or mental disorders. On the other hand, they have been reluctant to introduce tests to determine virginity and pregnancy tests, and even more so to introduce paternity tests that might bring into light manifestations of moral laxity within Egyptian society and jeopardize the future of illegitimate children. In conclusion, the main resistance to the reliance on modern medical evidence has not been the lack of modern knowledge and technologies or opposition to this, but rather traditional moral and social perceptions.

Shaker I, Scott JA, Reid M. Infant feeding attitudes of expectant parents: breastfeeding and formula feeding. *J Adv Nurs* 2004; 45(3):260-8. Abstract: BACKGROUND: Research has indicated that parental attitudes are strong predictors of choice of infant feeding. Identification and understanding of the infant feeding attitudes of mothers and their social networks should be an early step in the design and implementation of breastfeeding interventions. AIM: To compare the infant feeding attitudes of parents of breastfed infants with those of parents of formula fed infants. METHODS: A survey was carried out with a convenience sample of pregnant women (gestational age 8-12 weeks) attending three maternity clinics in Scotland in 2000. Expectant mothers and their partners (n = 108 couples) completed the 17 item Iowa Infant Feeding Attitude Scale. Demographic information was collected by face-to-face interview and the method of feeding at discharge from hospital was obtained from medical records. RESULTS: Parents of breastfed infants had more positive attitudes towards breastfeeding than parents of formula fed infants, and were more knowledgeable about the health benefits and nutritional superiority of breastfeeding. Fathers of both breastfed and formula fed infants were more likely than their partners to disapprove of women breastfeeding in public. Parents considered their chosen method of feeding to be the more convenient alternative. Mothers of formula fed infants were more likely to think that women who occasionally drink alcohol should not breastfeed. CONCLUSION: Parents of formula fed infants had several misconceptions about breastfeeding. Use of the Iowa Infant Feeding Attitude Scale could help health professionals identify and address these in infant feeding discussions in the early antenatal period. Efforts should be made to include fathers in these infant-feeding discussions.

Shalev AY, Tuval-Mashiach R, Hadar H. Posttraumatic stress disorder as a result of mass trauma. *J Clin Psychiatry* 2004; 65 Suppl 1:4-10. Abstract: There is a large body of literature on the psychological consequences of trauma experienced by individuals, but there are few studies of the acute and long-term effects of mass trauma on victimized communities. Acute stress reactions are expected, and overall resilience in the aftermath of major disasters is

the rule rather than the exception. However, the available literature on mass trauma suggests that certain factors may provide clues to identifying persons at greater risk for posttraumatic stress disorder (PTSD). The severity of the trauma and the accessibility of support systems may affect long-term outcome. In industrialized countries, mass violence caused by malicious human intent may be a more virulent precursor to PTSD than other types of mass trauma, such as technological or natural disasters. School-aged children, women, persons with existing psychiatric illness, those who experienced significant losses or threat to life, those who have insufficient psychological and social support systems, and persons who exhibit symptoms of functional impairment may be at greater risk for PTSD. The findings of a population study of 2 traumatized communities are discussed. Early intervention in communities suffering mass trauma should consist of general support and bolstering of the recovery environment rather than psychological treatment; some forms of early psychological interventions may worsen outcome. There is a great unmet need for treatment and intervention guidelines for victims of mass trauma, and well-designed studies are warranted.

Shapiro C. Organ transplantation in infants and children--necessity or choice: the case of K'aila Paulette. *Pediatr Nurs* 2005; 31(2):121-2. Notes: GENERAL NOTE: KIE: KIE Bib: organ and tissue transplantation; treatment refusal/minors

Sharav VH. The impact of the Food and Drug Administration Modernization Act on the recruitment of children for research. *Ethical Hum Sci Serv* 2003; 5(2):83-108.

Notes: GENERAL NOTE: KIE: 159 refs. GENERAL NOTE: KIE: KIE Bib: human experimentation/minors; human experimentation/regulation

Abstract: This article argues that contrary to the claims made by research stakeholders in industry, academia and government, the shift in public policy since the enactment of the Food and Drug Administration Modernization Act (FDAMA) of 1997 and its financial incentives to industry to test drugs on children, has had a deleterious impact on children's dignity, health and welfare. Those lucrative incentives offered an opportunity to accelerate the pace of FDA approval for pediatric drug marketing. FDAMA resulted in a radical shift in federal policy to accommodate an expansion of pediatric trials. Children who are precluded from exercising a human adult's right to informed consent to research are increasingly sought as test subjects even when the trials offer no potential benefit for them. Prior to FDAMA children were protected under federal regulations that prohibited their recruitment for experiments that were not in their best interest. This article discusses eight cases and controversies demonstrating that children have been subjected to

experiments that exposed them to pain, discomfort, and serious risks of harm. Babies have died testing a lethal heartburn drug; children have been subjected to "forced dose titration" in antidepressant drug trials that resulted in several suicide attempts. Toddlers are currently being subjected to methylphenidate dose tolerance tests without evidence of any pathological condition. Healthy teenagers are being exposed to antipsychotic drugs known to induce severe pathological side effects in speculative "schizophrenia prevention" experiments.

Shaw DS, Criss MM, Schonberg MA, Beck JE. The development of family hierarchies and their relation to children's conduct problems. *Dev Psychopathol* 2004; 16(3):483-500.

Abstract: Despite the intuitive richness of family systems theory, relatively little research has sought to test the validity of constructs theorized to be critical in the development of children's adjustment. One such cornerstone of structural and strategic family therapy is the family hierarchy. The present study investigated both the development of hierarchical structure in families from infancy to late middle childhood and relations between strong hierarchical structure and children's conduct problems. Using structural equation modeling, direct pathways to low hierarchical structure were evident for early caregiving behavior and parent-child conflict, with indirect associations present for parental adjustment, marital functioning, negative child behavior, and ecological disadvantage. In turn, family hierarchies were associated with youth antisocial behavior, an effect that was moderated by ethnic and neighborhood context. The results are discussed in reference to family systems' theory and implications for prevention and intervention.

Shaw JA. The legacy of child sexual abuse. *Psychiatry* 2004; 67(3):217-21.

Shaw WC, Semb G, Nelson P *et al.* The Eurocleft project 1996-2000: overview. *J Craniomaxillofac Surg* 2001; 29(3):131-40; discussion 141-2.

Abstract: INTRODUCTION: The original Eurocleft project, a European intercentre comparison study, revealed dramatic differences in outcome, which were a powerful stimulus for improvement in the services of respective teams. The study developed a preliminary methodology to compare practices and the potential for wider European collaboration including opportunities for the promotion of clinical trials and intercentre comparison was recognized by the European Commission. Therefore, the project: 'Standards of Care for Cleft Lip and Palate in Europe: Eurocleft' ran between 1996 and 2000 and aimed to promote a broad uplift in the quality of care and research in the area of cleft lip and palate. RESULTS: The results of the 1996-2000 project include: a register of services in Europe, with details of professionals and teams involved in cleft care, service organization, clinical

protocols and special facilities for research; a set of common Policy Statements governing clinical practice for European cleft teams, Practice Guidelines describing minimum recommendations for care that all European children with clefts should be entitled to and recommendations for Documentation governing minimum records that cleft teams should maintain; encouraging initial efforts to compare outcomes (results) of care between centres. A survey showed a wide diversity in models of care and national policies as well as clinical practices in Europe. Of the 201 centres that registered with the network, the survey showed 194 different protocols being followed for only unilateral clefts. CONCLUSION: Cleft services, treatment and research have undoubtedly suffered from haphazard development across Europe. Attainment of even minimum standards of care remains a major challenge in some communities and both the will to reform and a basic strategy to follow are overdue. It is hoped that the Eurocleft Consensus Recommendations reached during the present project will assist in improving the opportunities for tomorrow's patients. It is also hoped that the collaborative research now beginning under the European Commission's Framework V Programme will provide a focus for European researchers wishing to improve understanding, treatment and prevention of clefts of the lip, alveolus and palate in the years ahead.

Sheehan K, Kim LE, Galvin JP Jr. Urban children's perceptions of violence. *Arch Pediatr Adolesc Med* 2004; 158(1):74-7.

Abstract: OBJECTIVE: To determine how preadolescent urban children conceptualize and experience violence in their lives. DESIGN: This qualitative study reports the results of focus groups designed to examine perceptions of violence among preadolescent urban children. Program directors were trained to conduct the sessions using a semistructured script. All groups were audiotaped or videotaped. The summaries were analyzed for recurring themes. SETTING: A community-based visual arts program for children designed to be a secondary violence-prevention program. PARTICIPANTS: There were 12 focus groups of volunteer participants. Each consisted of 3 to 6 children aged 8 to 12 years, separated by sex and age. Fifty children participated: 27 boys and 23 girls. RESULTS: These children defined violence in a broader way than most adults would. Not only did the children identify shootings and stabbings as examples of violence, but they also considered violence to be any act that might hurt someone's feelings (such as cheating and lying) or any act accompanying violence (such as cursing and yelling). The boys and girls were very similar in their views except regarding the issue of intimate-partner violence. The girls were almost universally concerned about this issue, but the boys seemed noticeably unaware that intimate-partner violence was considered a form of violence. Most children felt safe at home, and almost no child felt safe

at school. They looked to trusted adults to keep them safe. CONCLUSIONS: Future investigators measuring the effect of violence-prevention activities on preteen children should be aware that their definition of violence may differ from that of young children and should be cognizant of potential sex differences, especially around the topic of intimate-partner violence. Those designing violence-prevention programs for children should consider engaging adult family members as well because children usually turn to them for safety.

Sheeshka J, Potter B, Norrie E, Valaitis R, Adams G, Kuczynski L. Women's experiences breastfeeding in public places. *J Hum Lact* 2001; 17(1):31-8. Abstract: This two-part field study compared researchers' recorded observations to mothers' perceptions of attention they received while publicly breastfeeding. In part 1, four breastfeeding and four bottle-feeding mothers each made eight restaurant visits. On average, there were more neutral looks from customers ( $P = .01$ ) during breastfeeding visits, but no differences in the amount of overtly negative or positive attention given during breastfeeding versus bottle feeding. In part 2, four breastfeeding mothers made a total of 24 visits to shopping malls. There were more neutral looks given while mothers were breastfeeding and more smiles and comments while they were not feeding, but no difference in total amount of attention received. Breastfeeding mothers acknowledged they had anticipated some undesirable attention but instead received little attention. Nevertheless, they felt "vulnerable" nursing in public. Certain proactive behaviors and personal attributes as well as support from other women enabled them to breastfeed successfully in public.

Shek DT. Beliefs about the causes of poverty in parents and adolescents experiencing economic disadvantage in Hong Kong. *J Genet Psychol* 2004; 165(3):272-91. Abstract: Over 2 consecutive years, parents and their adolescent children from 199 poor families in Hong Kong responded to the Chinese Perceived Causes of Poverty Scale, which assesses beliefs about the causes of poverty. The author abstracted 4 factors from the scale. Analyses showed that these factors (personal problems, exploitation, lack of opportunity, fate) were stable across time and across different samples. The author also found related subscales to be internally consistent. Regarding the effects of time, adolescents had weaker endorsement of the belief that poverty is caused by the personal problems of poor people over time. The author found parent-adolescent differences (parents vs. adolescents) and parental differences (fathers vs. mothers) regarding beliefs about the causes of poverty in terms of personal problems of poor people, exploitation, and fate.

Shek DT. Family functioning and psychological well-being,

school adjustment, and problem behavior in Chinese adolescents with and without economic disadvantage. *J Genet Psychol* 2002; 163(4):497-502. Abstract: Using an indigenously developed measure of family functioning, the author examined the association between family functioning and adolescent adjustment in 1,519 Chinese adolescents. Results showed that family functioning was significantly related to measures of adolescent psychological well-being (existential well-being, life satisfaction, self-esteem, sense of mastery, general psychiatric morbidity), school adjustment (perceived academic performance, satisfaction with academic performance, and school conduct), and problem behavior (delinquent and substance abuse behavior). Family functioning was generally more strongly related to measures of adolescent adjustment for adolescents with economic disadvantage than for adolescents without economic disadvantage.

Shek DT. Perceived parental control processes, parent-child relational qualities, and psychological well-being in Chinese adolescents with and without economic disadvantage. *J Genet Psychol* 2005; 166(2):171-88. Abstract: The author assessed the relationships between poverty and perceived parenting style, parent-child relationships, and adolescent psychological well-being in Chinese secondary school students ( $N = 3,017$ ). Participants completed questionnaires designed to assess (a) the degree to which their parents used monitoring, discipline, and other techniques to control their behavior; (b) the extent to which their parents attempted to control them in a way that undermined their psychological development; (c) the parent-child relational qualities, such as the child's readiness to communicate with the parents and perceived mutual trust; and (d) the child's psychological well-being. Although adolescents with economic disadvantage did not differ from adolescents without economic disadvantage on the maternal variables (except on parental knowledge and parental monitoring), adolescents whose families were receiving public assistance generally perceived paternal behavioral control and father-child relational qualities to be more negative than did adolescents who were not receiving public assistance. The author found psychological well-being (shown by hopelessness, mastery, life satisfaction, self-esteem) of adolescents experiencing economic disadvantage to be weaker than that of adolescents not experiencing economic disadvantage.

Sheldon S, Wilkinson S. Should selecting saviour siblings be banned? *J Med Ethics* 2004; 30(6):533-7.  
Notes: GENERAL NOTE: KIE: 25 refs.  
GENERAL NOTE: KIE: KIE Bib: genetic screening; organ and tissue donation; prenatal diagnosis  
Abstract: By using tissue typing in conjunction with preimplantation genetic diagnosis doctors are able to pick a human embryo for implantation which, if all goes well, will become a "saviour sibling", a brother or sister capable of donating life-saving tissue to an existing child. This paper addresses the question of whether this form of selection should be banned and concludes that it should not. Three main prohibitionist arguments are considered and found wanting: (a) the claim that saviour siblings would be treated as commodities; (b) a slippery slope argument, which suggests that this practice will lead to the creation of so-called "designer babies"; and (c) a child welfare argument, according to which saviour siblings will be physically and/or psychologically harmed.

Shelley DC, McCormick SR, LeGrand TS, Cardenas J, Peters JI. The effect of a pediatric asthma management program provided by respiratory therapists on patient outcomes and cost. *Heart Lung* 2005; 34(6):423-8.  
Abstract: OBJECTIVE: The objective was to determine whether a pediatric asthma disease management program (ADMP) provided by respiratory therapists can improve patient outcomes and reduce cost. DESIGN: This was a pre-and post-intervention observational study. METHODS: Hospitalizations, non-intensive care unit (ICU) hospital days, ICU days, emergency department visits, doctor's office visits, school days missed, and associated costs were collected on 18 children with moderate to severe asthma, ages 3 to 18 years, 12 months before and after implementation of the ADMP. The ADMP consisted of eight home visits for assessment, environmental review, and patient education. RESULTS: There were

significant reductions ( $P < .05$ ) in hospitalizations, hospitalization cost, ICU days, non-ICU days, length of stay, emergency department visits and cost, physician office visits and cost, and school days missed. CONCLUSIONS: A pediatric in-home ADMP provided by respiratory therapists can improve outcomes and reduce cost in patients with moderate to severe asthma.

Sheller B. Challenges of managing child behavior in the 21st century dental setting. *Pediatr Dent* 2004; 26(2):111-3.  
Abstract: This paper discussed factors influencing behavior management of the child dental patient. Pediatric dentists are affected by changes in: (1) society; (2) marketing and media; (3) communications and technology; and (4) parenting practices. Behavior of pediatric patients reflects fewer boundaries, less discipline and self-control, and lowered behavioral expectations by parents and contemporary culture. The insurance industry, regulatory bodies, legal system, dental staff, and pediatric dentist education are other influences on behavior management. Responses of the American Academy of Pediatric Dentistry (AAPD), which could support the pediatric dentist in the changing environment, include: (1) research; (2) continuing education for staff and dentists; (3) development of Internet accessible materials for the public; (4) legislative activity; (5) partnering with pediatric medicine to develop new behavior management strategies; (6) establishment of an AAPD Council on Child Behavior; and (7) ongoing critical reassessment of behavior issues by the AAPD.

Sherrard J, Ozanne-Smith J, Staines C. Prevention of unintentional injury to people with intellectual disability: a review of the evidence. *J Intellect Disabil Res* 2004; 48(Pt 7):639-45.  
Abstract: BACKGROUND: Recent research evidence shows that people with intellectual disability (ID) have double the unintentional injury risk of the general population and the risk is further increased in the presence of psychopathology and epilepsy. The pattern of injury and the circumstances surrounding an injury event in those with ID have some similarity with that of young children in the general population. Interventions to prevent injuries are an important health priority in this vulnerable population. This paper reviews evidence from injury prevention studies for people with ID and also considers the relevance of general population injury interventions for this population. METHOD: Information regarding injury prevention in both ID and general populations was identified using online systems and consultation with research and public health organizations. RESULTS: Few published studies were identified addressing the

issue of injury prevention for those with ID. Possible injury prevention strategies appropriate for the major causes of injury in the ID population were identified from the general population literature. While many environmental injury prevention strategies for young children in the general population are applicable to the population with ID, some may require design modification to ensure effectiveness. Other promising approaches include improved information for parents/carers, primary care physician counselling, and home visits by well-informed and motivated professionals. There may be injury prevention benefit from improved management of psychopathology and epilepsy. CONCLUSIONS: The issue of injury prevention for those with ID has not been addressed to the extent that the magnitude of the problem requires. Injury prevention programmes trialling a variety of evidence-based approaches and strategies are needed to protect the quality of life for the ID population and their families.

Sherriff A, Ott J. Artificial neural networks as statistical tools in epidemiological studies: analysis of risk factors for early infant wheeze. *Paediatr Perinat Epidemiol* 2004; 18(6):456-63.  
Notes: CORPORATE NAME: ALSPAC Study Team  
Abstract: Artificial neural networks (ANNs) are being used increasingly for the prediction of clinical outcomes and classification of disease phenotypes. A lack of understanding of the statistical principles underlying ANNs has led to widespread misuse of these tools in the biomedical arena. In this paper, the authors compare the performance of ANNs with that of conventional linear logistic regression models in an epidemiological study of infant wheeze. Data on the putative risk factors for infant wheeze have been obtained from a sample of 7318 infants taking part in the Avon Longitudinal Study of Parents and Children (ALSPAC). The data were analysed using logistic regression models and ANNs, and performance based on misclassification rates of a validation data set were compared. Misclassification rates in the training data set decreased as the complexity of the ANN increased:  $h = 0$ : 17.9%;  $h = 2$ : 16.2%;  $h = 5$ : 14.9%, and  $h = 10$ : 9.2%. However, the more complex models did not generalise well to new data sets drawn from the same population: validation data set misclassification rates:  $h = 0$ : 17.9%;  $h = 2$ : 19.6%;  $h = 5$ : 20.2% and  $h = 10$ : 22.9%. There is no evidence from this study that ANNs outperform conventional methods of analysing epidemiological data. Increasing the complexity of the models serves only to overfit the model to the data. It is important that a validation or test data set is used to assess the performance of highly complex ANNs to avoid overfitting.

Shields A, Ryan RM, Cicchetti D. Narrative representations of caregivers and emotion dysregulation as predictors of maltreated children's rejection by peers. *Dev Psychol* 2001; 37(3):321-37.

Abstract: This study examined whether maltreated children were more likely than nonmaltreated children to develop poor-quality representations of caregivers and whether these representations predicted children's rejection by peers. A narrative task assessing representations of mothers and fathers was administered to 76 maltreated and 45 nonmaltreated boys and girls (8-12 years old). Maltreated children's representations were more negative/constricted and less positive/coherent than those of nonmaltreated children. Maladaptive representations were associated with emotion dysregulation, aggression, and peer rejection, whereas positive/coherent representations were related to prosocial behavior and peer preference. Representations mediated maltreatment's effects on peer rejection in part by undermining emotion regulation. Findings suggest that representations of caregivers serve an important regulatory function in the peer relationships of at-risk children.

Shields J. The NAS EarlyBird Programme: partnership with parents in early intervention. *The National Autistic Society. Autism* 2001; 5(1):49-56.  
Abstract: Early intervention bridges the gap between early diagnosis and appropriate educational placement. The National Autistic Society has developed an autism-specific three-month parent package, the NAS EarlyBird Programme, that emphasizes partnership with parents. Six families participate in each three-month programme, which combines weekly group training sessions for parents with individualized home visits. During the programme parents learn to understand autism, to build social communication, and to analyse and use structure, so as to prevent inappropriate behaviours. The use of video and the group dynamic amongst families are important components of the programme. An efficacy study evaluated the pilot programme and further monitoring is in progress. Training courses in the licensed use of the NAS EarlyBird Programme are now available for teams of professionals with prior experience of autism. Strengths and weaknesses of the programme are discussed. This short-term, affordable package, with supporting evidence of efficacy, offers a model of early intervention that is very popular with parents.

Shifman P, Renaud T. Food-coping in post-emergency-phase camps. *Lancet* 2003; 361(9366):1392-3; author reply 1393.

Shifren K. Early caregiving and adult depression: good news for young caregivers. *Gerontologist* 2001; 41(2):188-90.  
Abstract: PURPOSE: Limited information is available on the effects of caregiving experiences on the adult development of caregivers under 21 years old in the United States. The current study provided an examination of the effects of youthful caregiving on the mental health of these persons when adults.

**DESIGN AND METHODS:** Twelve individuals, 23 to 58 years old, were given brief phone interviews with semistructured questions, and then they completed questionnaires on their early caregiving experiences and current mental health. To be included, respondents must have provided primary caregiving assistance (i.e., bathing, dressing, feeding, etc.) for at least one parent when the caregiver was under 21 years old. **RESULTS:** The findings showed that individuals were young caregivers for parents with a number of problems, ranging from dementia to drug abuse. Individuals reported more positive mental health than negative mental health, and only two individuals had scores indicative of clinical depressive symptoms. **IMPLICATIONS:** It appears that early caregiving experiences may not result in universally negative consequences in the adulthood of young caregivers.

Shifrin T. Slow but sure. *Health Serv J* 2003; 113(5841):13-4.

Shin DI, Huh SJ, Lee TS, Kim IY. Web-based remote monitoring of infant incubators in the ICU. *Int J Med Inform* 2003; 71(2-3):151-6. Abstract: A web-based real-time operating, management, and monitoring system for checking temperature and humidity within infant incubators using the Intranet has been developed and installed in the infant Intensive Care Unit (ICU). We have created a pilot system which has a temperature and humidity sensor and a measuring module in each incubator, which is connected to a web-server board via an RS485 port. The system transmits signals using standard web-based TCP/IP so that users can access the system from any Internet-connected personal computer in the hospital. Using this method, the system gathers temperature and humidity data transmitted from the measuring modules via the RS485 port on the web-server board and creates a web document containing these data. The system manager can maintain centralized supervisory monitoring of the situations in all incubators while sitting within the infant ICU at a work space equipped with a personal computer. The system can be set to monitor unusual circumstances and to emit an alarm signal expressed as a sound or a light on a measuring module connected to the related incubator. If the system is configured with a large number of incubators connected to a centralized supervisory monitoring station, it will improve convenience and assure meaningful improvement in response to incidents that require intervention.

Shipman K, Edwards A, Brown A, Swisher L, Jennings E. Managing emotion in a maltreating context: a pilot study examining child neglect. *Child Abuse Negl* 2005; 29(9):1015-29.

Abstract: **OBJECTIVE:** The primary goal of this pilot study was to examine emotion management skills (i.e., emotional understanding, emotion regulation) in

children who had experienced neglect and a control group to determine the ways that neglect may interfere with children's emotional development. **METHOD:** Participants included children 6--12 years of age and their mothers (neglect group, N=24; control, N=24). Participants completed questionnaires and an interview that assessed children's emotional understanding and emotion regulation. **RESULTS:** Findings indicated that neglected children, compared to their non-maltreated peers, demonstrated lower understanding of negative emotions (i.e., anger, sadness) and fewer adaptive emotion regulation skills. Further, neglected children expected less support and more conflict from mothers in response to displays of negative emotion and reported that they were more likely to attempt to inhibit the expression of negative emotion. **CONCLUSIONS:** Findings suggest that neglect may interfere with the normal acquisition of emotional understanding and emotion regulation skills, highlighting the importance of addressing these skills in the context of clinical intervention with neglected children.

Shipman KL, Zeman J. Socialization of children's emotion regulation in mother-child dyads: a developmental psychopathology perspective. *Dev Psychopathol* 2001; 13(2):317-36.

Abstract: This study investigated the socialization of children's emotion regulation in 25 physically maltreating and 25 nonmaltreating mother-child dyads. Maltreating mothers and their 6- to 12-year-old children were recruited from two parenting programs affiliated with Children's Protective Services with a control group matched on race, SES, child gender, and child age. Children and their mothers were interviewed individually about their (a) management of emotional expression, (b) strategies for coping with emotional arousal, and (c) anticipated consequences following emotional displays. Compared to controls, maltreated children expected less maternal support in response to their emotional displays, reported being less likely to display emotions to their mothers, and generated fewer effective coping strategies for anger. Maltreating mothers indicated less understanding of children's emotional displays and fewer effective strategies for helping children to cope with emotionally arousing situations than nonmaltreating mothers. Further, findings indicated that maternal socialization practices (e.g., providing support in response to children's emotional display, generating effective coping strategies for their child) mediate the relation between child maltreatment and children's regulation of emotional expression and emotional arousal. These findings suggest that children's emotion regulation strategies are influenced by their relationship with their social environment (e.g., physically maltreating, nonmaltreating) and that the experience of a physically maltreating relationship may interfere with children's emotional development.

Shriberg LD. Diagnostic markers for child speech-sound

- disorders: introductory comments. *Clin Linguist Phon* 2003; 17(7):501-5.  
 Abstract: The four papers in this issue report findings from a research programme on the etiological origins of child speech-sound disorders of currently unknown origin. Overviews elsewhere describe an evolving classificatory framework that posits six putative subtypes within this general domain of communicative disorders (cf. Shriberg, 2002). The following introductory comments provide brief historical and clinical perspectives on the primary objective of this research: the availability of a suite of computer-assisted diagnostic markers that clinicians and clinical researchers can use to classify six etiological subtypes of child speech-sound disorders.

 Abstract: A review of the current molecular diagnosis of cystic fibrosis including an introduction to cystic fibrosis, the gene function, the phenotypic variation, who should be screened for which mutation, newborn and couple screening, quality assurance, phenotype-genotype correlation, methods and method limitations, options, statements, recommendations, useful Websites and treatments.
- Shrimpton R. Evidence v. rights-based decision making for nutrition. *Proc Nutr Soc* 2003; 62(2):553-62.  
 Abstract: The need for an evidence base for human nutrition action is analysed in the context of human rights. Over the last 50 years the twin tracks of development, economical needs based and normative rights based, have come progressively closer in terms of goals and objectives, even if they do maintain different orientations and origins. The international human rights machinery is described, together with those parts that are of relevance to the right to food and nutrition. The role of the State in respecting, protecting and facilitating these rights is further described. The evidence base for the benefit of nutrition interventions during the fetal and infant period to the health and well-being of populations throughout life's course is briefly reviewed, and reasons why such a large body of evidence has not been acted upon are discussed. The power of nutrition is in prevention more than cure, and the prevention of nutritional deficiency is best suited to radical population-wide strategies rather than high-risk strategies targeted at individuals. The population-wide distribution of benefits of nutrition is in congruence with universality of human rights. In the UK much remains to be done to ensure that food and nutrition rights are realised, especially during the critical period of fetal and infant growth. What role the Nutrition Society might play in the realisation of these rights, including the creation of a robust evidence base for nutrition action, is further discussed.

- Shumba A. The nature, extent and effects of emotional abuse on primary school pupils by teachers in Zimbabwe. *Child Abuse Negl* 2002; 26(8):783-91.  
 Abstract: OBJECTIVE: The study seeks to determine the nature, extent and effects of emotional abuse; and who the perpetrators are in Zimbabwean primary schools. METHOD: Data collection was twofold because this involved reported cases of emotional abuse and the use of two questionnaires to collect data on the forms of emotional abuse perpetrated on pupils by teachers. First, data of reported cases of emotional abuse were collected from six regional offices of the Ministry of Education, Sport and Culture in Zimbabwe. The rationale was to determine forms of emotional abuse perpetrated on pupils by teachers in Zimbabwean primary schools. Second, the Teacher Trainees Questionnaire and the Teacher Questionnaire were administered to randomly selected samples of 150 primary school teacher trainees and 300 primary school teachers. Random numbers were used in the selection of the teachers and teacher trainees. The rationale for using teachers and teacher trainees was to make an in-depth analysis of the forms of emotional abuse perpetrated on pupils by teachers and to determine who the perpetrators are in this form of child abuse. In this study, emotional abuse shall refer to constant belittling of a pupil, the absence of a positive emotional atmosphere, verbal abuse, shouting, scolding, use of vulgar language, humiliation and negative labeling of pupils, and terrorizing of pupils by teachers in schools. RESULTS: The study found that the majority of teacher trainees and teachers believe that shouting, scolding, use of vulgar language, humiliation and negatively labeling of pupils as stupid, ugly, foolish is mainly done by female teachers in schools. However, 52.7% of the teacher trainees indicated that it is the male teachers who "use vulgar language on pupils." This study found some of the forms of emotional abuse that are perpetrated on pupils by teachers in schools. The findings seem to be consistent with the literature available on the gender of perpetrators associated with this form of child abuse. CONCLUSION: It is clear that emotional abuse exists in Zimbabwean primary schools and female teachers appear to be the main perpetrators of this form of child abuse. This form of child abuse may involve one perpetrator and a series of victims.
- Siddiqi S, Haq IU, Ghaffar A, Akhtar T, Mahaini R. Pakistan's maternal and child health policy: analysis, lessons and the way forward. *Health Policy* 2004; 69(1):117-30.  
 Abstract: An estimated 400,000 infant and 16,500 maternal deaths occur annually in Pakistan. These translate into an infant mortality rate and maternal mortality ratio that should be unacceptable to any state.

Disease states including communicable diseases and reproductive health (RH) problems, which are largely preventable account for over 50% of the disease burden. The analysis of Pakistan's maternal and child health (MCH) and family planning (FP) policy covers the period 1990-2002, and focuses on macroeconomic influences, priority programs and gaps, adequacy of resources, equity and organizational aspects, and the process of policy formulation. The overall MCH/FP policy is well directed. MCH/FP has been a priority in all policies; resource allocation, although unacceptably low, has substantially increased during the last decade; and there is a progressive shift from MCH to the reproductive health (RH) agenda. Areas in need of improvement include greater use of evidence as a basis for policy; increased priority to nutrition programs, measures to reduce neonatal and perinatal mortality, provision of emergency obstetric care, availability of skilled birth attendants, and a clear policy on integrated management of childhood illnesses. Enhanced planning capacity, development of a balanced human resource, improved governance to reduce staff absenteeism and frequent transfers, and a greater role of the private sector in the provision of services are some organizational aspects that need the governments' consideration. There are several lessons to be learnt: (i) Ministries of Health need sustained stewardship and well-documented evidence to protect cuts in resource allocation; (ii) frequent policy announcement sends inappropriate signals to managers and weakens ongoing implementation; (iii) MCH/FP policies unless informed by evidence and participation of interest groups are unlikely to address gaps in programs; (iv) distributional and equity objectives of MCH/FP be addressed while setting overall national goals; (v) institutional capacity is a vital ingredient in translating MCH/FP policies into effective services. The suggested strategic directions emphasize, among others, the need for a comprehensive MCH/FP framework; strengthened stewardship in ministry of health, cost-effective strategies to address the gaps identified and doubling of the public sector resource allocation to MCH/FP over the next 5 years. The ability to ensure delivery of quality health services remains the biggest challenge in the Pakistani health sector. Unless sound policies are backed by well-functioning programs they are likely to become a victim of poor implementation.

Siegel RM, Joseph EC, Routh SA *et al.* Screening for domestic violence in the pediatric office: a multipractice experience. *Clin Pediatr (Phila)* 2003; 42(7):599-602.

Abstract: The purpose of our study was to screen for domestic violence (DV) in 4 different pediatric practice settings. Women who accompanied their children to well-child visits were eligible. The women were screened with a 6-question tool previously piloted by our group, which included questions on partner abuse, child abuse, and pet abuse. Over a 1-year period, 435 women were screened. Of these women, 95 (22%)

described DV at some point in their lives. Sixty-nine (16%) reported abuse longer than 2 years before the screen and 26 (6%) reported more recent abuse. While 11 of 117 women screened in the more affluent private practice reported a history of past abuse, no women in that group reported DV occurring within 24 months. The proportion of women reporting violence did not differ significantly by site, but the proportion of patients reporting new violence was significantly lower at the private practice site by Chi-square analysis. In conclusion, women screened in a variety of pediatric settings will disclose DV. Recent abuse is more likely to be reported in settings with indigent patients. All pediatricians should be screening for DV and have protocols in place to offer women the services they need if DV is revealed.

Sieminski AL, Hebbel RP, Gooch KJ. Improved microvascular network in vitro by human blood outgrowth endothelial cells relative to vessel-derived endothelial cells. *Tissue Eng* 2005; 11(9-10):1332-45. Abstract: Evidence suggests that bone marrow-derived cells circulating in adult blood, sometimes called endothelial progenitor cells, contribute to neovascularization in vivo and give rise to cells expressing endothelial markers in culture. To explore the utility of blood-derived cells expressing an endothelial phenotype for creating tissue-engineered microvascular networks, we employed a three-dimensional in vitro angiogenesis model to compare microvascular network formation by human blood outgrowth endothelial cells (HBOECs) with three human vessel-derived endothelial cell (EC) types: human umbilical vein ECs (HUVECs), and adult and neonatal human microvascular ECs. Under every condition investigated, HBOECs within collagen gels elongated significantly more than any other cell type. Under all conditions investigated, gel contraction and cell elongation were correlated, with HBOECs demonstrating the largest generation of force. HBOECs did not exhibit a survival advantage, nor did they enhance elongation of HUVECs when the two cell types were cocultured. Network formation of both HBOECs and HUVECs was inhibited by blocking antibodies to alpha2beta1, but not alpha(v)beta3, integrins. Taken together, these data suggest that superior network exhibited by HBOECs relative to vessel-derived endothelial cells is not due to a survival advantage, use of different integrins, or secretion of an autocrine/paracrine factor, but may be related to increased force generation.

Silk JS, Sessa FM, Morris AS, Steinberg L, Avenevoli S. Neighborhood cohesion as a buffer against hostile maternal parenting. *J Fam Psychol* 2004; 18(1):135-46. Abstract: This study explored the moderating effects of children's neighborhoods on the link between hostile parenting and externalizing behavior. Participants were 1st- or 2nd-grade children in an urban northeastern community. Children were administered the Parenting

and Neighborhood scales of the Child Puppet Interview, and mothers completed questionnaires on neighborhood quality and parenting practices. Census tract measures of neighborhood quality and teachers' reports of children's externalizing behavior also were obtained. Results indicated that children's and mothers' perceptions of neighborhood involvement-cohesion buffered the link between hostile parenting and externalizing problems. Children's externalizing behavior was unrelated to census tract variables. Findings highlight the protective effect of neighborhood social cohesion and the utility of including young children's perspectives in research on neighborhoods and families.

Silverman K, Schonberg SK. Adolescent children of drug-abusing parents. *Adolesc Med* 2001; 12(3):485-91. Abstract: The effects of a substance-abusing parent on a child are wide-spread, and unfortunately they follow that child well into adolescence and adulthood. Cognitive difficulty, poor judgment, and conduct problems are but a few of the sequelae, and similar results are seen whether the drug is alcohol or cocaine or another illicit substance. In addition to affecting the biology of the adolescent from the perinatal period, parental substance abuse often causes a disrupted, chaotic home, financial insecurity, and exposure of the teen to illegal substances and violence. The emotional toll on the adolescent is steep, and the overall cost to the health care system is enormous. Ultimately, many of these adolescents progress to substance abuse themselves. Health care providers need to be sensitive to the possibility of substance abuse in the home, and should aggressively pursue early treatment/therapy options for those teens at risk.

Silverman RD. No more kidding around: restructuring non-medical childhood immunization exemptions to ensure public health protection. *Ann Health Law* 2003; 12(2):277-94, table of contents. Notes: GENERAL NOTE: KIE: 112 fn. GENERAL NOTE: KIE: KIE Bib: immunization Abstract: Professor Silverman's article examines the complex challenges faced by U.S. policymakers attempting to balance the public health protections of mandatory childhood immunization programs with the legal, religious, philosophical, and practical concerns raised by permitting non-medical exemptions under the programs. The article begins with a discussion of the history of childhood immunization programs, and continues by describing the inconsistency of enforcement of state immunization laws and exemptions. The author analyzes recent cases from New York, Wyoming, and Arkansas, and discusses how these decisions both pose threats to these programs' public health protections, while also offering

insight into potential problems for other state vaccination programs. Professor Silverman concludes by advocating that states adopt an "informed refusal" approach to vaccination exemption as a way of improving immunity protections, while respecting the autonomy rights of those who wish to opt out of the program.

Simmons TM, Novins DK, Allen J. Words have power: (re)-defining serious emotional disturbance for American Indian and Alaska Native children and their families. *Am Indian Alsk Native Ment Health Res* 2004; 11(2):59-64.

Abstract: Circles of Care grantees were provided the opportunity to develop a locally relevant definition of serious emotional disturbance that would be used to define what type of emotional, behavioral, and mental disability would be required to receive services. After conducting detailed assessments of the definition in the guidance for applicants GFA and the definitions used by others in their respective states, seven of the nine grantees developed their own local, project-specific definitions through the participation of community focus groups and Advisory Councils. The six definitions for SED developed by rural grantees all included American Indian and Alaska Native concepts specific to each tribal community's culture; the urban grantee's definition was purposely focused for reaching out to non-professional members of the community. This opportunity for the communities to redefine SED not only provided each community with a definition which would be more culturally specific, but also proved to be an extraordinarily exercise in empowerment and self-determination.

Simoens WA, Wuyts FL, De Beuckeleer LH, Vandevenne JE, Bloem JL, De Schepper AM. MR features of peripheral nerve sheath tumors: can a calculated index compete with radiologist's experience? *Eur Radiol* 2001; 11(2):250-7.

Abstract: The aims of this study were, firstly, to provide a formula (neurogenic index) based on MR characteristics used in daily routine for predicting whether a soft tissue tumor is neurogenic or not, secondly, to test prospectively the performance of this

formula, and thirdly, to compare this performance with that of radiologists experienced in MR imaging of soft tissue tumors. Retrospectively, MR images of 70 neurogenic and 70 non-neurogenic soft tissue tumors were evaluated in random order by two teams of two observers each. A neurogenic index (NI) was calculated based on those MR parameters that showed no or minor interobserver variability. Subsequently, three investigators in concert used the NI in a validation group of 15 neurogenic and 22 nonneurogenic soft tissue tumors. The same team, based on their own experience, tried to differentiate in the same validation group neurogenic from non-neurogenic soft tissue tumors. This was expressed in a subjective score (SS). Sensitivity, specificity, and predictive values were calculated. NI comprised spread (intra- or extracompartmental), distribution, fluid-fluid levels, homogeneity on T2-weighted images (WI), highest signal intensity (SI) on T1WI, lowest SI on T2WI, and delineation on T2WI. In the validation group, NI had a sensitivity of 88.6%, a specificity of 52.0%, a positive predictive value (PPV) of 54.1%, and a negative predictive value (NPV) of 84.6% for neurogenic tumors. The subjective score SS was superior and had a sensitivity of 93.3%, a specificity of 77.2%, a PPV of 73.7%, and a NPV of 94.4%. Our NI was less accurate than the SS; however, the low number of false-negative diagnoses for neurogenic tumors warrants continued efforts in development of neural networks.

Simon D, Adams AM, Madhavan S. Women's social power, child nutrition and poverty in Mali. *J Biosoc Sci* 2002; 34(2):193-213.

Abstract: While the macro-level association between poverty and child malnutrition is well-established, the concept of 'poverty' and its operationalization in terms of measures of socioeconomic status shed little or no light on the mechanisms through which malnutrition is created and/or prevented. This paper investigates a woman's social power, one such mechanism that may mediate the impact of poverty on childhood nutrition. This micro-level factor is examined using survey data on 402 children 5 years of age and younger and their 261 Fulbe mothers in rural Mali. A conceptual model of social power is developed and used to test the hypothesis that a mother's social power can predict her child's nutritional status.

Simon J, Sood S, Yoon MK *et al.* Vitrectomy for dense vitreous hemorrhage in infancy. *J Pediatr Ophthalmol Strabismus* 2005; 42(1):18-22. Abstract: PURPOSE: To report clinical data, including etiology and visual outcome, in newborns requiring vitrectomy for dense vitreous hemorrhage. METHODS: In this retrospective case series, we surveyed subscribers to the American Association for Pediatric Ophthalmology and Strabismus ListServe regarding patients under their care. RESULTS: A total of 28 eyes of 21 patients were included. Most common

etiologies were thrombocytopenia, shaken baby syndrome, and birth trauma. In 9 cases (12 eyes), the vitreous hemorrhage was idiopathic. Mean time between diagnosis and surgery was 1.4 months. Complications included strabismus, cataract, glaucoma, high myopia, and retinal detachment. Recognition visual acuities were available for 8 eyes: 20/25 (2 eyes), 20/30, 20/40 (2 eyes), 20/60 (2 eyes), and 20/100. One eye had no light perception. CONCLUSIONS: The etiologies encountered in our patients were similar to those reported previously. Visual outcomes were much worse in cases with retinal complications. Other patients had better visual outcomes. Despite potential surgical and postoperative complications, this series demonstrates favorable visual outcomes can be achieved following early vitrectomy in this setting.

Simonoff E. Gene-environment interplay in oppositional defiant and conduct disorder. *Child Adolesc Psychiatr Clin N Am* 2001; 10(2):351-74, x. Abstract: Oppositional defiant and conduct disorder is a disturbance in behavior that is characterized by aggressive and antisocial acts. At present, genetic research on conduct disorder has raised more questions than it has answered, and basic questions such as the heritability of childhood antisocial behavior cannot yet be answered with certainty. Current research, however, has consistently highlighted the importance of gene-environment interplay in antisocial behavior.

Simpson KR. Time out: it's time well spent. *MCN Am J Matern Child Nurs* 2004; 29(4):272.

Sinal SH, Woods CR. Human papillomavirus infections of the genital and respiratory tracts in young children. *Semin Pediatr Infect Dis* 2005; 16(4):306-16. Abstract: Human papillomavirus (HPV) causes papillomas (warts) on the skin and respiratory mucosal surfaces (laryngeal and oral papillomas) in addition to condyloma acuminata (anogenital warts). HPV has become one of the most common sexually transmitted diseases in adults. Vertical transmission from mother to infant during birth is well recognized. Laryngeal papillomas are the most common tumors of the larynx in children worldwide, and recurrent lesions are common occurrences. Anogenital warts in children are problematic in that child sexual abuse is a potential means of acquisition, but many cases are acquired perinatally. Postnatal acquisition by nonsexual means also can occur. The likelihood of sexual abuse as the mode of acquisition increases with increasing age in childhood. The virus infects primarily epithelial cells, where it can exist as a long-term latent infection that can reactivate or persist actively (even subclinically), with resultant accumulation of host chromosomal mutations. The latter accounts for the oncogenic potential of a number of HPV types, and childhood infections may lead to neoplasia later in life.

Regression of papillomas over the course of months to years is the usual natural course. Numerous treatments are available, but most do not prevent persistent infection or problematic recurrences. Multivalent HPV vaccines have been developed, and early results of clinical trials appear to be very promising.

Sinclair J, Green J. Understanding resolution of deliberate self harm: qualitative interview study of patients' experiences. *BMJ* 2005; 330(7500):1112. Abstract: OBJECTIVE: To explore the accounts of those with a history of deliberate self harm but who no longer do so, to understand how they perceive this resolution and to identify potential implications for provision of health services. DESIGN: Qualitative in-depth interview study. SETTING: Interviews in a community setting. PARTICIPANTS: 20 participants selected from a representative cohort identified in 1997 after an episode of deliberate self poisoning that resulted in hospital treatment. Participants were included if they had no further episodes for at least two years before interview. RESULTS: We identified three recurrent themes: the resolution of adolescent distress; the recognition of the role of alcohol as a precipitating and maintaining factor in self harm; and the understanding of deliberate self harm as a symptom of untreated or unrecognised illness. CONCLUSION: Patients with a history of deliberate self harm who no longer harm themselves talk about their experiences in terms of lack of control over their lives, either through alcohol dependence, untreated depression, or, in adolescents, uncertainty within their family relationships. Hospital management of deliberate self harm has a role in the identification and treatment of depression and alcohol misuse, although in adolescents such interventions may be less appropriate.

Sindelar HA, Abrantes AM, Hart C, Lewander W, Spirito A. Motivational interviewing in pediatric practice. *Curr Probl Pediatr Adolesc Health Care* 2004; 34(9):322-39.

Singer E, Doornenbal J, Okma K. Why do children resist or obey their foster parents? The inner logic of children's behavior during discipline. *Child Welfare* 2004; 83(6):581-610.

Abstract: This article discusses a study of children's perspectives on disciplinary conflicts with their foster parents. Most children accept parental authority, but they also defend their personal autonomy and loyalties to peers. In this study, only birthchildren told real-life stories about fierce resistance to get their own way. Fierce resistance among foster children was motivated by inner conflicts and confusion. Obedience among foster children often derived from fear of punishment or a feeling of impotence. The authors discuss the theoretical and pedagogical implications of these findings.

Singer LT, Hawkins S, Huang J, Davillier M, Baley J.

Developmental outcomes and environmental correlates of very low birthweight, cocaine-exposed infants. *Early Hum Dev* 2001; 64(2):91-103. Abstract: Fetal cocaine exposure may have differentially adverse effects on developmental outcomes of very low birthweight (VLBW) infants. As part of a longitudinal study, 31 cocaine-positive very low birthweight infants, and age, race and socioeconomic status matched VLBW controls enrolled at birth were followed. Neonatal maternal-child interactions, concurrent maternal psychological characteristics and environmental factors conceptualized as important for child outcome were assessed as well as standard developmental outcomes at 3 years. In the neonatal period, cocaine-exposed VLBW infants who remained in maternal custody tended to be rated as less responsive and their mothers as less nurturing, less emotionally available and with a tendency to use more maladaptive coping mechanisms than nonexposed VLBW infants. At follow-up, cocaine-exposed VLBW children were delayed in cognitive, motor and language development compared to controls. Almost half (45%) of the exposed children scored in the range of mental retardation compared to 16% of the comparison VLBW children. The persistent cognitive, motor and language delays of the cocaine-exposed VLBW children, combined with the poorer behavioral interactions of cocaine-using women with their infants in the neonatal period, indicate a need for increased developmental surveillance of cocaine-exposed VLBW infants with a focus on maternal drug treatment and parenting interventions.

Singh M. Ethical and social issues in the care of the newborn. *Indian J Pediatr* 2003; 70(5):417-20. Abstract: Ethical and social issues are based upon a system of moral values that serve the best interests of the society in a humane and compassionate manner. The ethical decisions should be based upon the well-enunciated principles of beneficence, non-maleficence, parental autonomy, correct medical facts and justice. In view of our economic constraints, we should follow the philosophy of utilitarian ethics based on the concept of "value for money" and focus our resources and efforts for the care of salvageable babies. Nevertheless, we should try to ensure equitable development of health care of neonates at all levels, and NICU facilities should be developed in the country in a phased manner. In order to ensure justice and cost-effectiveness, the narrow principles of "best interest" of the child should be replaced by the concept of global beneficence to the family, society and the state. Neonatologists are often faced with a large number of ethical issues and dilemmas in the care of critically sick newborn babies and they should be resolved jointly by taking nurses, sub-speciality colleagues and family members into confidence. The technology should not be allowed to further dehumanize medicine and we must establish rapport and provide emotional support to the family members by showing our concern, sympathy and

compassion in the care of their critically sick and extremely preterm babies. It is desirable that all the medical and nursing schools in the country should initiate regular education programs in the field of behavioural sciences, communication techniques and medical ethics for the benefit of graduate and postgraduate medical and nursing students.

Singhal N, Oberle K, Burgess E, Huber-Okraïneç J. Parents' perceptions of research with newborns. *J Perinatol* 2002; 22(1):57-63.

Abstract: **OBJECTIVE:** To examine beliefs and attitudes of parents about research with babies. **STUDY DESIGN:** Survey of 72 parents of newborn babies in the neonatal intensive care unit (NICU), and 159 parents of normal newborns using instrument designed for the study. The instrument included questions with graded responses and five research scenarios with varied risks and benefits. Statistical analysis included chi(2) analysis and Fisher's exact test. **RESULTS:** Parents showed generally favorable attitudes toward research with babies. There were few differences between the two groups of parents, but there was a trend toward more trust in doctors by "NICU parents." Couples with newborns in NICU were significantly more likely to enroll their newborn in a study involving moderate risk and possible major direct benefit. Almost a third of the sample in both groups was willing to enroll their newborn in a study with moderate risk and no direct benefit. **CONCLUSION:** Parents believe research is necessary and want to be asked for consent, but many feel they have limited knowledge and would depend on their physician's advice. The fact, that some might enroll their newborn in a study involving a risky procedure that would not benefit the newborn, supports the notion of vulnerability and emphasizes the fact that physicians must be alert to the possibility of coercion and undue influence.

Sinha M, Kennedy CS, Ramundo ML. Artificial neural network predicts CT scan abnormalities in pediatric patients with closed head injury. *J Trauma* 2001; 50(2):308-12.

Abstract: **BACKGROUND:** Artificial neural networks (ANNs) use nonlinear statistical modeling techniques to explore relationships in complex clinical situations. This study compared predictive ability of a trained ANN model to that of physician prediction of cranial computed tomographic (CT) scan abnormalities in children with head injury. **METHODS:** A prospective cohort of 351 patients who presented with head trauma and underwent CT scans were studied. All pertinent data on historical and demographic information, and clinical features were recorded. Emergency department physicians used clinical judgment to record pretest probability of abnormal CT scans for all patients prospectively. Similar data from a retrospective chart review of 382 patients with head injury in the immediate preceding year were collected and used to

train the ANN. Data from the prospective study was used to validate the ANN, construct a logistic regression model, and compare physician prediction. **RESULTS:** Forty-five (12.9%) of 351 patients had abnormal CT scans. In predicting CT scan abnormality, the ANN model was more sensitive (82.2%) compared with physician prediction (62.2%). **CONCLUSION:** ANNs may serve as a useful aid for decision support for emergency physicians in predicting intracranial abnormalities in closed head injury.

Siqueira LM, Rolnitzky LM, Rickert VI. Smoking cessation in adolescents: the role of nicotine dependence, stress, and coping methods. *Arch Pediatr Adolesc Med* 2001; 155(4):489-95.

Abstract: **OBJECTIVES:** To compare perceived reasons for continued smoking and withdrawal symptoms between current smokers and quitters in an inner-city adolescent population. To examine the relationship of nicotine dependence, stress, and coping methods between smokers and quitters and, using the Transtheoretical Model of Change, among adjacent smoking cessation stages. **DESIGN:** A cross-sectional study using a self-administered questionnaire. **PARTICIPANTS:** The study comprised 354 clinic patients between the ages of 12 and 21 years who reported past or present smoking. **MAIN OUTCOME MEASURES:** Demographic characteristics, smoking status, perceived reasons for continued smoking, attempts to quit, and withdrawal symptoms, as well as standardized scales assessing nicotine dependence, stress, and coping methods. **RESULTS:** The overall prevalence of smoking in this population was 26%. Smokers were significantly more likely to report smoking more cigarettes per day as well as higher levels of physical addiction ( $P < .01$ ), greater levels of perceived stress ( $P < .02$ ), and less use of cognitive coping methods ( $P < .02$ ) than quitters ( $P < .005$ ). However, comparison of consecutive stages revealed a significant difference only between precontemplation and contemplation in cognitive coping methods ( $P < .01$ ). Three of 20 withdrawal symptoms (cravings, difficulty dealing with stress, and anger) were reported more frequently among current smokers who had attempted to quit in the last 6 months than among former smokers ( $P < .01$ ). **CONCLUSION:** Interventions for inner-city adolescents who smoke should be designed to target those with the highest levels of nicotine dependence, stress, and decreased use of cognitive coping methods because they are the least likely to quit on their own, rather than developing stage-specific models.

Sirois S. Autoassociator networks: insights into infant cognition. *Dev Sci* 2004; 7(2):133-40.

Abstract: This paper presents autoassociator neural networks. A first section reviews the architecture of these models, common learning rules, and presents sample simulations to illustrate their abilities. In a second section, the ability of these models to account

for learning phenomena such as habituation is reviewed. The contribution of these networks to discussions about infant cognition is highlighted. A new, modular approach is presented in a third section. In the discussion, a role for these learning models in a broader developmental framework is proposed.

Sirois S, Mareschal D. An interacting systems model of infant habituation. *J Cogn Neurosci* 2004; 16(8):1352-62.

Abstract: Habituation and related procedures are the primary behavioral tools used to assess perceptual and cognitive competence in early infancy. This article introduces a neurally constrained computational model of infant habituation. The model combines the two leading process theories of infant habituation into a single functional system that is grounded in functional brain circuitry. The HAB model (for Habituation, Autoassociation, and Brain) proposes that habituation behaviors emerge from the opponent, complementary processes of hippocampal selective inhibition and cortical long-term potentiation. Simulations of a seminal experiment by Fantz [Visual experience in infants: Decreased attention familiar patterns relative to novel ones. *Science*, 146, 668-670, 1964] are reported. The ability of the model to capture the fine detail of infant data (especially age-related changes in performance) underlines the useful contribution of neurocomputational models to our understanding of behavior in general, and of early cognition in particular.

Sjoberg RL. [The Cleveland case as a lesson. Single cases and case series can be simple to take in but they are not suitable to secure the cause-effect relationship]. *Lakartidningen* 2004; 101(41):3166-7.

Sjoberg RL. [Sexual experiences in connection with sexual abuse can delay the disclosure]. *Lakartidningen* 2003; 100(17):1549.

Sjoberg RL, Lindblad F. Delayed disclosure and disrupted communication during forensic investigation of child sexual abuse: a study of 47 corroborated cases. *Acta Paediatr* 2002; 91(12):1391-6.  
Abstract: AIM: To study factors of relevance for the understanding of disclosure of child sexual abuse. METHODS: Cases from a Swedish district court involving 47 children in which allegations of child sexual abuse had been corroborated by a confession from the defendant were studied. RESULTS: Delayed disclosure was related to a close relationship with the perpetrator and young age at the first experience of abuse. Disrupted communication during the police interview was related to less violent abuse.

CONCLUSION: The findings highlight the importance of social factors in children's disclosure of sexual abuse.

Skene L. Ownership of human tissue and the law. *Nat Rev Genet* 2002; 3(2):145-8.  
Notes: GENERAL NOTE: KIE: 23 refs.  
GENERAL NOTE: KIE: KIE Bib: biomedical research; informed consent; organ and tissue donation  
Abstract: Genetic researchers and medical practitioners often need to obtain access to stored human tissue without consent from the people concerned. But the laws that relate to the ownership of, and control over, stored human tissue are at present unclear, especially in the light of recent cases and inquiries. Here, I discuss how the law might be clarified, and argue that the law should allow stored human tissue to be used without consent, providing that this occurs with ethical approval and that the confidentiality of the donor is protected.

Skinner H, Biscope S, Poland B. Quality of internet access: barrier behind internet use statistics. *Soc Sci Med* 2003; 57(5):875-80.  
Abstract: The rapid growth of the Internet is increasingly international with young people being the early adopters in most countries. However, the quality of Internet access looms as a major barrier hidden behind Internet use statistics. The goal of this study was to provide an in-depth evaluation of young people's perspectives on using the Internet to obtain health information and resources (e-health). Using an inductive qualitative research design, 27 focus groups were conducted in Ontario, Canada. The 210 young participants were selected to reflect diversity in age, sex, geographic location, cultural identity and risk. A major finding was how the quality of Internet access influenced young people's ability to obtain health information and resources. Quality of Internet access was affected by four key factors: 1. Privacy, 2. Gate-keeping, 3. Timeliness and 4. Functionality. Privacy was particularly relevant to these young people in getting access to sensitive health information (e.g. sexual activities). Variations in access quality also impacted participation in mutual support, fostering social networks and getting specific health questions answered. These results serve as a warning about using Internet penetration statistics alone as a measure of access. Concerted attention is needed on improving the quality of Internet access for achieving the potential of e-health. This is imperative for addressing the digital divide affecting populations both within countries and globally between countries.

Skopp NA, McDonald R, Manke B, Jouriles EN. Siblings in domestically violent families: experiences of interparent conflict and adjustment problems. *J Fam Psychol* 2005; 19(2):324-33.  
Abstract: This research examines whether siblings in

domestically violent families differ in experiences of interparent conflict and whether such differences are associated with differences in children's adjustment. Participants included 112 sibling pairs and their mothers temporarily residing in domestic violence shelters. Children completed measures of their experiences of interparent conflict, and children and mothers reported on children's adjustment problems. Cross-sibling correlations for experiences of interparent conflict were low to moderate. Sibling differences in threat appraisals of interparent conflict were associated with sibling differences in internalizing problems. Differences in self-blame appraisals were associated with differences in internalizing and externalizing problems. The direction of the relations indicated that the sibling who felt more threatened by or more at fault for interparent conflict experienced more adjustment problems. These findings suggest the potential utility of individually assessing sibling experiences of interparent conflict and tailoring interventions individually.

Slote KY, Cuthbert C, Mesh CJ, Driggers MG, Bancroft L, Silverman JG. Battered mothers speak out: participatory human rights documentation as a model for research and activism in the United States. *Violence Against Women* 2005; 11(11):1367-95. Abstract: This article describes the work of the Battered Mothers' Testimony Project, a multiyear effort that documented human rights violations against battered women and their children in the Massachusetts family court system. This article (a) presents the Battered Mothers' Testimony Project's participatory human rights methodology as an alternative model for research and activism on violence against women and children in the United States, (b) summarizes the authors' findings and human rights analysis of how the Massachusetts family courts handled custody and visitation in specified cases involving partner and child abuse, and (c) discusses U.S. obligations under international human rights law and the value of a human rights approach to violence against women and children in the United States.

Slovak K. Gun violence and children: factors related to exposure and trauma. *Health Soc Work* 2002; 27(2):104-12. Abstract: The study discussed in this article investigated the relationship between access to firearms and parental monitoring on rural youths' exposure to gun violence and examined the effect of gun violence exposure on the mental health of these youths. A survey was administered to rural students who participated in a student assistance program (n = 162) that provided in-school support groups for students in grades 6 through 12. Results indicated that a substantial number of students were exposed to gun violence and exposure was significantly related to firearm access and parental monitoring. Furthermore, gun violence exposure was significantly associated with trauma

among the youths. Implications for social workers include advising high-risk clients and their families on gun removal and safe storage practices.

Slovak K, Singer M. Gun violence exposure and trauma among rural youth. *Violence Vict* 2001; 16(4):389-400. Abstract: This study compared rural youth exposed to gun violence and rural youth not exposed to gun violence on a number of variables: anger, anxiety, dissociation, depression, posttraumatic stress, total trauma, violent behavior, parental monitoring, and levels of violence in the home, school, and community. One-fourth (25%) of the rural youth in this study reported having been exposed to gun violence at least once. Youth exposed to gun violence reported significantly more anger, dissociation, posttraumatic stress, and total trauma. In addition, youth exposed to the violence of guns reported significantly higher levels of violent behaviors and exposure to violence in other settings and also reported lower levels of parental monitoring. The present study contributes to the growing body of literature addressing the stereotype that rural communities are not immune to the violence of firearms. This stereotype acts as a barrier to mental health practice, research, and policy issues in rural communities.

Slovic TL. Controversial aspects of child abuse. *Pediatr Radiol* 2001; 31(11):759.

Smallbone SW, Wortley RK. Onset, persistence, and versatility of offending among adult males convicted of sexual offenses against children. *Sex Abuse* 2004; 16(4):285-98. Abstract: Official sexual and nonsexual offense histories and confidential self-report data on sexual offending were obtained on 207 adult males serving sentences for sexual offenses against children (98 intrafamilial, 72 extrafamilial, and 37 mixed-type offenders). The mean self-reported age when offenders first had sexual contact with a child was 32.2 years (median = 31 years; range = 10-63 years). The mean age at first conviction for any offense was 30.5 years (median = 27 years, range = 12-66 years), and the mean age at first conviction for a sexual offense was 37.3 years (median = 37 years; range = 15-76 years). Sixty-nine percent (n = 143) of the combined sample had at least one previous conviction, and 80% of these (n = 114) had first been convicted for a nonsexual offense. ANCOVA revealed a systematic pattern of onset with first convictions for any offense preceding first sexual contact with a child. Taken together, results indicate that, in general, adult child molesters (a) begin sexual offending in their 30s, (b) have already become involved in nonsexual crime by the time they first have sexual contact with a child, (c) are criminally versatile, and (d) vary considerably in their persistence with respect to both sexual and nonsexual offending.

Smetana JG, Daddis C. Domain-specific antecedents of parental psychological control and monitoring: the role of parenting beliefs and practices. *Child Dev* 2002; 73(2):563-80.

Abstract: This research examined the effects of domain-differentiated beliefs about legitimate parental authority and ratings of restrictive parental control on adolescent- and mother-reported psychological and behavioral control. The influence of parenting beliefs and practices regarding socially regulated (moral and conventional) and ambiguously personal (multifaceted and personal) issues was examined in 93 middle-class African American early adolescents (M = 13.11 years, SD = 1.29) and their mothers, who were followed longitudinally for 2 years. Domain-specific parenting beliefs and ratings predicted adolescent-reported maternal psychological control and parental monitoring, but the nature and direction of the relations differed. Adolescents who rated parents as more restrictive in their control of personal issues and who believed that parents should have less legitimate authority over these issues rated their mothers as higher in psychological control. In contrast, more adolescent-reported parental monitoring was associated with gender (being female) and adolescents' beliefs that parents have more legitimate authority to regulate personal issues. As expected, adolescent age and gender influenced mother-reported monitoring and psychological control; in addition, the effects of mothers' ratings of restrictive control on both psychological control and monitoring were moderated by gender. The results indicate that psychological control and monitoring can be understood in terms of the particular behaviors that are controlled, as well as the style in which control is exercised.

Smillie FI, Elderfield AJ, Patel F *et al.* Lymphoproliferative responses in cord blood and at one year: no evidence for the effect of in utero exposure to dust mite allergens. *Clin Exp Allergy* 2001; 31(8):1194-204. Abstract: BACKGROUND: Maternal allergen exposure beyond the 22nd week of pregnancy may be important in foetal T cell priming. Allergen-specific cord blood mononuclear cell (CBMC) immunoproliferative responses without corresponding bacterial antigen responses (tetanus toxoid), have been suggested as evidence of in utero sensitization. OBJECTIVES: To investigate the relationship between lymphoproliferative responses at birth and at 1 year with maternal and 1-year infants house dust mite allergen exposure. METHODS: Home visits and dust sampling were performed by the 20th week of pregnancy, immediately after birth, and then at 1 years of age. Der p 1 was assayed using a two-site immunometric ELISA. CBMC immunoproliferative responses (AIM V serum-free medium; 1 x 10<sup>5</sup> cells/well) were measured for 225 neonates (171 had a high risk of atopy (HR)—both parents skin test positive; 59 had a low risk of atopy (LR) - both parents skin test negative, no history of atopy) by 3H-Thymidine

(1microCi/well) incorporation after stimulation in primary culture with phytohaemagglutinin (PHA) (1 microg/mL), house dust mite [HDM] extract (30 microg/mL), immunopurified Der p 1 (30 microg/mL), Tetanus toxoid (TT) (alum free, 30 Lf/mL) or vehicle. Blood was collected from 144 infants at the age of 1 years and stimulated proliferative responses were assessed using the same procedure. RESULTS: PHA-stimulated lymphoproliferative response was significantly lower in HR compared to LR neonates (mean difference 38%, 95% CI 15%-54%; P = 0.003); significantly lower proportion of positive CBMC responses to HDM occurred in LR than in HR neonates (30.4% vs. 46.6%; P = 0.034). There was no relationship between Der p 1 levels in maternal bed and CBMC immunoproliferative responses, despite the 21 000-fold range of maternal Der p 1 exposure. No significant differences in magnitude, or in proportion of positive responses to any stimulant were observed between the neonates at low, medium or high tertile of allergen exposure. Immunoproliferative responses at birth were not predictive of 1-year PBMC responses. There was no relationship between maternal allergen exposure in pregnancy and 1-year PBMC proliferative responses. However, the proportion of positive proliferative responses at 1 years significantly increased with increasing infant Der p 1 exposure at 1 years. CONCLUSION: These results indicate that the magnitude of immunoproliferative responses are unrelated to maternal mite allergen exposure and cannot be used as evidence for in utero sensitization to inhalant allergens. The immunoproliferative responses at 1 year seem to shift away from the genetically influenced responses at birth towards responses to specific stimulants which correlate with environmental exposure to those specific stimulants. These data support the concept of sensitization to inhalant allergens occurring in early life, but not in utero.

Smith A, Coveney J, Carter P, Jolley G, Laris P. The Eat Well SA project: an evaluation-based case study in building capacity for promoting healthy eating. *Health Promot Int* 2004; 19(3):327-34. Abstract: The term 'capacity building' is used in the health promotion literature to mean investing in communities, organizations and structures to enhance access to knowledge, skills and resources needed to conduct effective health programs. The Eat Well SA project aimed to increase consumption of healthy food by children, young people and their families in South Australia. The project evaluation demonstrated that awareness about healthy eating among stakeholders across a range of sectors, coalitions and partnerships to promote healthy eating and sustainable programs had been developed. The project achievements were analysed further using a capacity-building framework. This analysis showed that partnership development was a key strategy for success, leading to increased problem-solving capacity among key stakeholders and workers from education, child care, health, transport

and food industry sectors. It was also a strategy that required concerted effort and review. New and ongoing programs were initiated and institutionalized within other sectors, notably the child care, vocational education and transport sectors. A model for planning and evaluating nutrition health promotion work is described.

Smith CA, Ireland TO, Thornberry TP. Adolescent maltreatment and its impact on young adult antisocial behavior. *Child Abuse Negl* 2005; 29(10):1099-119. Abstract: STATEMENT OF PROBLEM: Childhood maltreatment is known to be a risk factor for a range of later problems, but much less is known about adolescent maltreatment. The present study aims to investigate the impact of adolescent maltreatment on antisocial behavior, while controlling for prior levels of problem behavior as well as sociodemographic characteristics. METHODS: Data are from the Rochester Youth Development Study, a cohort study of the development of problem behaviors in a sample of 1,000 urban youth followed from age 13 into adulthood. Subjects include 68% African American, 17% Hispanic, and 15% White youth. This analysis includes a maximum of 884 subjects, of whom 9.3% had substantiated maltreatment reports in adolescence. Among the maltreated adolescents, 14 experienced sex abuse, 36 experienced physical abuse, and 32 were neglected or emotionally abused. Outcomes explored in late adolescence (ages 16-18) and young adulthood (ages 20-22) include arrest, self-reported general and violent offending, and illicit drug use. Control variables include prior levels of these outcomes as well as sociodemographic characteristics like poverty, parent education, and caregiver changes. RESULTS: Logistic regression analysis determined that experiencing any substantiated maltreatment during adolescence increases the odds of arrest, general and violent offending, and illicit drug use in young adulthood, even controlling for sociodemographic characteristics and prior levels of problem behavior. Different types of adolescent maltreatment, including neglect, appear to produce similar adverse behavioral consequences. CONCLUSIONS: Adolescent maltreatment necessitates increased attention in view of its enduring and potentially wide-ranging impact on the life span.

Smith EP, Atkins J, Connell CM. Family, school, and community factors and relationships to racial-ethnic attitudes and academic achievement. *Am J Community Psychol* 2003; 32(1-2):159-73. Abstract: This study examined family, school, and community factors and the relationships to racial-

ethnic attitudes and academic achievement among 98 African American fourth-grade children. It has been posited that young people who feel better about their racial-ethnic background have better behavioral and academic outcomes, yet there is a need for more empirical tests of this premise. Psychometric information is reported on measures of parent, teacher, and child racial-ethnic attitudes. Path analysis was used to investigate ecological variables potentially related to children's racial-ethnic attitudes and achievement. Parental education and level of racial-ethnic pride were correlated and both were related to children's achievement though in the final path model, only the path from parental education level was statistically significant. Children whose teachers exhibited higher levels of racial-ethnic trust and perceived fewer barriers due to race and ethnicity evidenced more trust and optimism as well. Children living in communities with higher proportions of college-educated residents also exhibited more positive racial-ethnic attitudes. For children, higher racial-ethnic pride was related to higher achievement measured by grades and standardized test scores, while racial distrust and perception of barriers due to race were related to reduced performance. This study suggests that family, school, and community are all important factors related to children's racial-ethnic attitudes and also to their academic achievement.

Smith EP, Gorman-Smith D, Quinn WH, Rabiner DL, Tolan PH, Winn DM. Community-Based multiple family groups to prevent and reduce violent and aggressive behavior: the GREAT Families Program. *Am J Prev Med* 2004; 26(1 Suppl):39-47. Notes: CORPORATE NAME: Multisite Violence Prevention Project Abstract: This paper describes the targeted intervention component of GREAT Schools and Families. The intervention-GREAT Families-is composed of 15 weekly multiple family group meetings (e.g., 4-6 families per group) and addresses parenting practices (discipline, monitoring), family relationship characteristics (communication, support, cohesion), parental involvement and investment in their child's schooling, parent and school relationship building, and planning for the future. High-risk youth and their families-students identified by teachers as aggressive and socially influential among their peers-were targeted for inclusion in the intervention. The paper describes the theoretical model and development of the intervention. Approaches to recruitment, engagement, staff training, and sociocultural sensitivity in work with families in predominantly poor and challenging settings are described. The data being collected throughout the program will aid in examining the theoretical and program processes that can potentially mediate and moderate effects on families. This work can inform us about necessary approaches and procedures to engage and support families in efforts to reduce individual and school grade-level violence and

- aggression.

- Smith-Khuri E, Iachan R, Scheidt PC *et al*. A cross-national study of violence-related behaviors in adolescents. *Arch Pediatr Adolesc Med* 2004; 158(6):539-44. Abstract: BACKGROUND: Violent behavior among adolescents is a significant problem worldwide, and a cross-national comparison of adolescent violent behaviors can provide information about the development and pattern of physical violence in young adolescents. OBJECTIVES: To determine and compare frequencies of adolescent violence-related behaviors in 5 countries and to examine associations between violence-related behaviors and potential explanatory characteristics. Design, Setting, and PARTICIPANTS: Cross-sectional, school-based nationally representative survey at ages 11.5, 13.5, and 15.5 years in 5 countries (Ireland, Israel, Portugal, Sweden, and the United States). MAIN OUTCOME MEASURES: Frequency of physical fighting, bullying, weapon carrying, and fighting injuries in relation to other risk behaviors and characteristics in home and school settings. RESULTS: Fighting frequency among US youth was similar to that of all 5 countries (nonfighters: US, 60.2%; mean frequency of 5 countries, 60.2%), as were the frequencies of weapon carrying (noncarriers: US, 89.6%; mean frequency of 5 countries, 89.6%) and fighting injury (noninjured: US, 84.5%; mean frequency of 5 countries, 84.6%). Bullying frequency varied widely cross-nationally (nonbullies: from 57.0% for Israel to 85.2% for Sweden). Fighting was most highly associated with smoking, drinking, feeling irritable or bad tempered, and having been bullied. CONCLUSIONS: Adolescents in 5 countries behaved similarly in their expression of violence-related behaviors. Occasional fighting and bullying were common, whereas frequent fighting, frequent bullying, any weapon carrying, or any fighting injury were infrequent behaviors. These findings were consistent across countries, with little cross-national variation except for bullying rates. Traditional risk-taking behaviors (smoking and drinking) and being bullied were highly associated with the expression of violence-related behavior.

- Smith PK, Ananiadou K, Cowie H. Interventions to reduce school bullying. *Can J Psychiatry* 2003; 48(9):591-9. Abstract: In the last 2 decades, school bullying has become a topic of public concern and research around the world. This has led to action to reduce the problem. We review interventions targeted at the school level (for example, whole school policy, classroom climate, peer support, school tribunal, and playground improvement), at the class level (for example, curriculum work), and at the individual level (for example, working with specific pupils). Effectiveness of interventions has been sporadically assessed. We review several systematically evaluated, large-scale, school-based intervention programs. Their effectiveness has varied, and we consider reasons for this. We suggest ways to improve the evaluation and comparability of studies, as well as the effectiveness of future interventions.
- Snodgrass SR, Vedanarayanan VV, Parker CC, Parks BR. Pediatric patients with undetectable anticonvulsant blood levels: comparison with compliant patients. *J Child Neurol* 2001; 16(3):164-8. Abstract: Undetectable anticonvulsant blood levels indicate sustained noncompliance (several consecutive doses missed). We compared 91 consecutive outpatients with epilepsy and undetectable anticonvulsant blood levels to 100 patients seen during the same time period, verified as compliant by acceptable serum levels. We hypothesized that pay status, application for Supplemental Security Income, patient age, history of missed appointments, and functional status would differ between compliant and noncompliant patients. We were surprised to find large differences between clinic and insurance patients and between Caucasian and non-Caucasian patients. The 100 compliant patients included 44 Caucasian and 56 non-Caucasian patients, whereas only 9 of 91 noncompliant patients were Caucasian, and only 9 had insurance, compared to 32 compliant patients. Applications for Supplemental Security Income and history of missed appointments were significantly associated with noncompliance, but patient age, seizure type, and seizure control were not. Uninsured Caucasians were more often compliant than non-Caucasians were. Many noncompliant patients had mild epilepsy, which was reportedly doing well. Race and pay status were closely correlated. Several noncompliant females became pregnant, whereas no compliant patients did. Compliant patients were much more likely to be accompanied by a parent or caretaker on clinic visits than noncompliant patients. Noncompliant patients had at least one acceptable subsequent serum level, although 2 patients with intractable epilepsy had undetectable serum levels on three or more occasions. Noncompliance may respond to discussion and advice. We reviewed 124 episodes of

undetectable drug levels in the 91 noncompliant patients. Eighteen of these resulted in hospitalization, but in 25 cases, we were told that there had been no seizures since the preceding visit. Many noncompliant patients have infrequent seizures, even if they take little or no medication. Socioeconomic status influences health, life expectancy, and educational success, but it has been claimed to be irrelevant to compliance and adherence issues in epilepsy. Our data and the experience of other centers with childhood diabetes suggest that socioeconomic, racial, and family factors influence compliance or adherence to treatment for many chronic conditions. Educational efforts and support for parents at the start of anticonvulsant treatment may improve compliance. Uninsured patients missed more appointments and were much more likely to be noncompliant than insured patients. Attention to the special problems of Medicaid and minority children is needed.

Snyder A, Bossomaier T, Mitchell DJ. Concept formation: 'object' attributes dynamically inhibited from conscious awareness. *J Integr Neurosci* 2004; 3(1):31-46. Abstract: We advance a dominant neural strategy for facilitating conceptual thought. Concepts are groupings of "object" attributes. Once the brain learns such critical groupings, the "object" attributes are inhibited from conscious awareness. We see the whole, not the parts. The details are inhibited when the concept network is activated, ie. the inhibition is dynamic and can be switched on and off. Autism is suggested to be the state of retarded concept formation. Our model predicts the possibility of accessing nonconscious information by artificially disinhibiting (turning off) the inhibiting networks associated with concept formation, using transcranial magnetic brain stimulation (TMS). For example, this opens the door for the restoration of perfect pitch, for recalling detail, for acquiring accent-free second languages beyond puberty, and even for enhancing creativity. The model further shows how unusual autistic savant skills as well as certain psychopathologies can be due respectively to privileged or inadvertent access to information that is normally inhibited from conscious awareness.

Snyder J, Cramer A, Afrank J, Patterson GR. The contributions of ineffective discipline and parental hostile attributions of child misbehavior to the development of conduct problems at home and school. *Dev Psychol* 2005; 41(1):30-41. Abstract: Data were collected in a longitudinal study of 134 boys and 132 girls and their families during kindergarten and first grade. Four hours of parent-child interaction were coded to ascertain parent discipline practices. A structured interview assessed maternal attributions about child behavior. Maternal ratings of child conduct problems at kindergarten entry reliably predicted the mother's subsequent hostile attributions concerning child misbehavior and use of ineffective discipline tactics. Ineffective maternal discipline and

the interaction of ineffective discipline and hostile attribution predicted growth in child conduct problems at home during kindergarten and first grade. Changes in teacher-reported and observed child conduct problems at school during kindergarten and first grade were predicted by growth in conduct problems at home and by the interaction of ineffective discipline and hostile attribution.

Sobin C, Kiley-Brabeck K, Daniels S, Blundell M, Anyane-Yeboa K, Karayiorgou M. Networks of attention in children with the 22q11 deletion syndrome. *Dev Neuropsychol* 2004; 26(2):611-26. Abstract: The 22q11 chromosomal deletion syndrome (22q11 DS) is associated with learning disabilities and a complex neuropsychological profile. Previous findings have suggested that executive attention deficits might underlie other neurocognitive anomalies. We administered the child Attention Network Test (ANT) to 52 children ages 5.0 to 11.5, 32 22q11 DS children (19 girls) and 20 controls (13 girls) and assessed the efficiency of segregated executive, orienting, and alerting networks. We hypothesized that 22q11 DS children have impaired executive network efficiency as compared to control siblings. The internal validity of the child ANT was confirmed for this population. Analysis of variance results showed significant main effects for flanker and cue types and no interaction effect in either 22q11 DS children or control siblings. Compared to control siblings, 22q11 DS children had significantly larger (less efficient) executive network scores, significantly increased errors on only incongruent trials, and a significant correlation between executive network scores and accuracy. The implications of these findings for future neurocognitive studies of 22q11 DS children are considered.

Soderberg S, Kullgren G, Salander Renberg E. Childhood sexual abuse predicts poor outcome seven years after parasuicide. *Soc Psychiatry Psychiatr Epidemiol* 2004; 39(11):916-20.

Abstract: BACKGROUND: There is substantial empirical research linking borderline personality disorder with prolonged mental instability and recurrent suicidality. At the same time, a growing body of observations links borderline personality disorder to sexual abuse and other forms of abuse and trauma in childhood. The aim of this study was to investigate among patients admitted for parasuicide the predictive value for outcome 7 years after the parasuicide of a diagnosis of borderline personality disorder compared to the predictive value of a history of childhood sexual abuse. METHODS: Semi-structured interviews were conducted at the time of the index parasuicide, with follow-up interviews 7 years later. In addition, information was collected from medical records at the

psychiatric clinic. A logistic regression analysis was used to assess the specific influence of the covariates borderline personality disorder, gender and reported childhood sexual abuse on the outcome variables. RESULTS: Univariate regression analysis showed higher odds ratios for borderline personality disorder, female gender and childhood sexual abuse regarding prolonged psychiatric contact and repeated parasuicides. A combined logistic regression model found significantly higher odds ratios only for childhood sexual abuse with regard to suicidal ideation, repeated parasuicidal acts and more extensive psychiatric support. CONCLUSION: The findings support the growing body of evidence linking the characteristic symptoms of borderline personality disorder to childhood sexual abuse, and identify sexual abuse rather than a diagnosis of borderline personality disorder as a predictor for poor outcome after a parasuicide. The findings are relevant to our understanding and treatment of parasuicide patients, especially those who fulfil the present criteria for borderline personality disorder.

Soderstrom H, Blennow K, Sjodin AK, Forsman A. New evidence for an association between the CSF HVA:5-HIAA ratio and psychopathic traits. *J Neurol Neurosurg Psychiatry* 2003; 74(7):918-21. Abstract: OBJECTIVES: To replicate the relation between the CSF HVA:5-HIAA ratio and psychopathic traits previously reported in a pilot group of 22 perpetrators of violent crimes. METHODS: CSF monoamine metabolite concentrations in another 28 violent and sexual offenders, aged 45 or below, referred to pretrial forensic psychiatric investigation, were compared to features of psychopathy according to the Psychopathy Checklist-Revised (PCL-R). RESULTS: Our previous finding was repeated in the new study group, where the HVA:5-HIAA ratio was strongly associated with psychopathic traits ( $r = 0.50$ ,  $p = 0.010$ ), particularly its behavioural aspects ( $r = 0.523$ ,  $p = 0.004$ ). In subsamples of individuals from both study groups who had no medication ( $n = 25$ ) or no current axis I disorder, including a history of mood disorder or substance dependence ( $n = 21$ ), the HVA:5-HIAA ratio remained strongly associated with all psychopathy factors but most closely with the behavioural features. Retrospective assessments of childhood disruptive symptomatology, such as attention deficit hyperactivity disorder or conduct disorder, analysed in relation to the monoamine metabolites, showed the same association with the HVA:5-HIAA ratio. CONCLUSIONS: Violent and aggressive behavioural traits with childhood onset and adult expression as psychopathic features are associated with changed activity in the brain dopaminergic system, possibly as a result of serotonergic dysregulation.

Soderstrom H, Nilsson T, Sjodin AK, Carlstedt A, Forsman A. The childhood-onset neuropsychiatric background

to adulthood psychopathic traits and personality disorders. *Compr Psychiatry* 2005; 46(2):111-6. Abstract: Childhood conduct disorder (CD) and adult psychopathic traits according to the Psychopathy Checklist Revised (PCL-R) were the closest psychiatric covariates to repeated violent crimes and aggression among offenders under forensic psychiatric investigation in Sweden. As psychopathy is not included in the present psychiatric diagnostic systems, we compared total and factor PCL-R scores to Axis I disorders, including childhood-onset neuropsychiatric disorders, and to Axis II personality disorders, to establish the convergence of psychopathic traits with other psychiatric diagnoses, and to identify possible unique features. Psychopathic traits were positively correlated with bipolar mood disorder and negatively with unipolar depression. The total PCL-R scores as well as the Factor 2 (unemotionality) and Factor 3 (behavioral dyscontrol) scores were significantly correlated with attention-deficit/hyperactivity disorder, Asperger's syndrome/high-functioning autistic traits, CD, substance abuse, and the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition Cluster B personality disorders. The interpersonal Factor 1 showed none of these correlations and may capture features that are specific to psychopathy, distinguishing core psychopathy from other diagnostic definitions.

Soderstrom H, Sjodin AK, Carlstedt A, Forsman A. Adult psychopathic personality with childhood-onset hyperactivity and conduct disorder: a central problem constellation in forensic psychiatry. *Psychiatry Res* 2004; 121(3):271-80. Abstract: To describe lifetime mental disorders among perpetrators of severe inter-personal crimes and to identify the problem domains most closely associated with aggression and a history of repeated violent criminality, we used structured interviews, clinical assessments, analyses of intellectual functioning, medical and social files, and collateral interviews in 100 consecutive subjects of pretrial forensic psychiatric investigations. Childhood-onset neuropsychiatric disorders [attention-deficit/hyperactivity disorder (AD/HD), learning disability, tics and autism spectrum disorders] affected 55% of the subjects and formed complex comorbidity patterns with adult personality disorders [including psychopathic traits according to the Psychopathy Checklist (PCL-R)], mood disorders and substance abuse. The closest psychiatric covariates to high Lifetime History of Aggression (LHA) scores and violent recidivism were the PCL-R scores and childhood conduct disorder (CD). Behavioral and affective PCL-R factors were closely associated with childhood AD/HD, CD, and autistic traits. The results support the notion that childhood-onset social and behavioral problems form the most relevant psychiatric symptom cluster in relation to pervasive adult violent behavior, while late-onset mental disorders are more often associated with single acts of violent or sexual aggression.

Solagberu BA, Ayorinde RO. Tuberculosis of the spine in Ilorin, Nigeria. *East Afr Med J* 2001; 78(4):197-9. Abstract: BACKGROUND: Data on tuberculosis (TB) of the spine from Nigeria is scanty despite the endemicity of the disease. OBJECTIVE: To highlight hospital data on spinal tuberculosis. DESIGN: A ten-year retrospective study of records on spinal TB from the medical records, orthopaedic and medical wards was done. The clinical notes, radiographs and haematology results of the patients were analysed. SETTING: University of Ilorin Teaching Hospital, Ilorin, Nigeria. SUBJECTS: All patients treated for spinal TB in the hospital from January 1990 to December 1999 were studied. RESULTS: Fifty patients were seen, 24 males and 26 females, age range 1.5-70 years (mean 27.1 +/- 22.8 years). Peak prevalence (30%) was in the first decade. Twenty seven patients had complete clinical data in their case notes. Twelve patients had paraplegia and three had concomitant pulmonary TB. The lumbar spine was the commonest site of involvement. Two thirds (18 patients) had positive mantoux test. Twenty three patients had chemotherapy but a third was lost to follow up within two months. Twenty one patients (77.8%) had difficulty obtaining the prescribed drugs due to financial difficulties. No patient had surgical intervention. CONCLUSION: Spinal TB is still a common disease in Nigeria with unacceptable laxity in control measures. There is need for patient health education, contact tracing, provision of free anti-TB drugs and a general improvement in the economy to reduce the prevalence of spinal TB in the country.

Solbakk JH. Use and abuse of empirical knowledge in contemporary bioethics. *Med Health Care Philos* 2004; 7(1):5-16.

Notes: GENERAL NOTE: KIE: KIE Bib: AIDS/human experimentation; human experimentation/foreign countries; human experimentation/research design  
Abstract: In 1997 a debate broke out about the ethical acceptability of using placebo as a comparative alternative to establish effective treatment in trials conducted in developing countries for the purpose of preventing perinatal HIV-transmission. The debate has now been going on for more than five years. In spite of extensive and numerous attempts at resolving the controversy, the case seems far from being settled. The aim of this paper is to provide an updated account of the debate, by identifying empirical arguments employed in the controversy and by critically assessing their use in the debate. A notion of resolution of moral conflicts will be introduced that makes it possible to give a more positive verdict on the moral results of this controversy. Finally, the procedural problem of safeguarding the selection of empirical arguments against undue forms of normative bias will be addressed.

Soldera M, Dalgarrondo P, Correa Filho HR, Silva CA. 862

[Use of psychotropics drugs among students: prevalence and associated social factors]. *Rev Saude Publica* 2004; 38(2):277-83. Abstract: OBJECTIVE: To determine the prevalence of the heavy use of drugs among elementary and high school students in a sample of public and private schools, and to identify associated demographic, psychological, cultural and social factors. METHODS: This report describes a cross-sectional study using an intention-type sampling technique that compared public schools in central and peripheral areas and private schools. An anonymous self-administered questionnaire was applied. The sample consisted of 2,287 elementary and high school students in the city of Campinas in 1998. Heavy use of drugs was defined as the use of drugs on 20 or more days during the 30 days preceding the survey (WHO, 1981). For the statistical analysis, polytomous logistic regression analysis (logit model) was utilized to identify factors that influenced this manner of using drugs. RESULTS: Heavy use of legal and illegal drugs was found as follows: alcohol (11.9%), tobacco (11.7%), marijuana (4.4%), solvents (1.8%), cocaine (1.4%), medications (1.1%) and ecstasy (0.7%). The heavy use of drugs was greatest among students at the city-center public school who had daytime jobs and studied in the evenings. These students were in the A and B socioeconomic classes and had had little religious education during childhood. CONCLUSIONS: Greater availability of cash and specific socialization patterns were identified as factors associated with the heavy use of drugs among students.

Solodiuk J, Curley MA. Pain assessment in nonverbal children with severe cognitive impairments: the Individualized Numeric Rating Scale (INRS). *J Pediatr Nurs* 2003; 18(4):295-9. Abstract: Children's Hospital Boston began a major pain assessment and management initiative 3 years ago: Pain assessment and management are considered one of the institution's primary standards of care. The initiative included State of the Science meetings with internationally renowned nursing pain researchers and clinicians. These meetings generated nursing staff interest in specific applications of what is known about pain; how evidence-based knowledge can be used to ask population-specific clinical questions; and how an evidence-based approach can be applied to systematically develop, implement, and assess interventions that suit a population's clinical needs. This article is an example of an evidence-based pain assessment project at Children's Hospital Boston that focused on nonverbal children with cognitive impairments. After developing a clinical question, the authors did a literature review and a benchmarking analysis of best practice. The pilot of an adapted, existing pain assessment tool is described in this article.

Solum LL, Schaffer MA. Ethical problems experienced by

school nurses. *J Sch Nurs* 2003; 19(6):330-7. Abstract: This study explored school nurses' experience of ethical conflict in school nursing through interviews with six school nurses. The study examined how school nurses resolved ethical problems and the rationale used to resolve them. Emergent themes of ethical problems were professional relationship conflicts, delegation to and supervision of health assistants, child protection reporting, maintaining confidentiality, Do Not Resuscitate policy, and pressure to work outside of nursing practice standards. School nurses did not use ethical decision-making models in resolving conflict but demonstrated the use of professional standards, ethical principles, and personal values as rationale to resolve ethical problems. Results of this study suggested that school nurses would benefit from additional knowledge about ethical decision-making models. School nurses would also profit from hearing each other's voices through dialogue about ethical problems and decision making.

Songok EM, Fujiyama Y, Tukei PM *et al.* The use of short-course zidovudine to prevent perinatal transmission of human immunodeficiency virus in rural Kenya. *Am J Trop Med Hyg* 2003; 69(1):8-13. Abstract: To determine the feasibility of using short-course zidovudine (ZDV) to prevent mother-to-child transmission of human immunodeficiency virus (HIV) in a breastfeeding population in a rural area in Kenya, pregnant mothers attending clinics in seven health centers in western Kenya between 1996 and 1998 were requested to volunteer for participation in this study. The HIV-infected mothers were given a daily dose of 400 mg of ZDV starting at 36 weeks of gestation and another 300 mg every three hours intrapartum. After delivery, mothers and their children were followed-up and clinically monitored every 3-4 months for two years, and child and mother mortality rates were analyzed. Of the 825 mothers who consented, 216 (26.2%) were infected with HIV. Of those infected, 51 (23.6%) took the full prescribed dose, 69 (31.9%) took only the prenatal dose, and the remaining 96 (44.4%) did not take any dose. Failure to take ZDV was attributed mainly to delivery occurring earlier than expected, while non-compliance to the intrapartum dose was due to mothers giving birth at home and fear of traditional birth attendants. By the end of the second year, 75 HIV-exposed children (34.7%) and 33 HIV-infected mothers (15.3%) had died. The HIV-free survival of children at 24 months was significantly associated with mother survival ( $P < 0.001$ ) and prenatal ZDV compliance ( $P < 0.003$ ). Our findings suggest that implementation of programs for prevention of mother-to-child transmission of HIV in rural areas of Africa need to consider the various socioeconomic and cultural barriers that may prevent successful uptake of antiretroviral prophylaxes. Similarly, the rapid disease progression in mothers may eliminate the increase in child survival due to ZDV prophylaxis.

Sood B, Delaney-Black V, Covington C *et al.* Prenatal alcohol exposure and childhood behavior at age 6 to 7 years: I. dose-response effect. *Pediatrics* 2001; 108(2):E34.

Abstract: OBJECTIVE: Moderate to heavy levels of prenatal alcohol exposure have been associated with alterations in child behavior, but limited data are available on adverse effects after low levels of exposure. The objective of this study was to evaluate the dose-response effect of prenatal alcohol exposure for adverse child behavior outcomes at 6 to 7 years of age. METHODS: Beginning in 1986, women attending the urban university-based maternity clinic were routinely screened at their first prenatal visit for alcohol and drug use by trained research assistants from the Fetal Alcohol Research Center. All women reporting alcohol consumption at conception of at least 0.5 oz absolute alcohol/day and a 5% random sample of lower level drinkers and abstainers were invited to participate to be able to identify the associations between alcohol intake and child development. Maternal alcohol, cigarette, and illicit drug use were prospectively assessed during pregnancy and postnatally. The independent variable in this study, prenatal alcohol exposure, was computed as the average absolute alcohol intake (oz) per day across pregnancy. At each prenatal visit, mothers were interviewed about alcohol use during the previous 2 weeks. Quantities and types of alcohol consumed were converted to fluid ounces of absolute alcohol and averaged across visits to generate a summary measure of alcohol exposure throughout pregnancy. Alcohol was initially used as a dichotomous variable comparing children with no prenatal alcohol exposure to children with any exposure. To evaluate the effects of different levels of exposure, the average absolute alcohol intake was relatively arbitrarily categorized into no, low ( $>0$  but  $<0.3$  fl oz of absolute alcohol/day), and moderate/heavy ( $\geq 0.3$  fl oz of absolute alcohol/day) for the purpose of this study. Six years later, 665 families were contacted. Ninety-four percent agreed to testing. Exclusions included children who missed multiple test appointments, had major congenital malformations (other than fetal alcohol syndrome), possessed an IQ  $>2$  standard deviations from the sample mean, or had incomplete data. The Achenbach Child Behavior Checklist (CBCL) was used to assess child behavior. The CBCL is a parent questionnaire applicable to children ages 4 to 16 years. It is widely used in the clinical assessment of children's behavior problems and has been extensively used in research. Eight syndrome scales are further grouped into Externalizing or undercontrolled (Aggressive and Delinquent) behavior and Internalizing or overcontrolled (Anxious/Depressed, Somatic Complaints, and Withdrawn) behaviors. Three syndromes (Social, Thought, and Attention Problems) fit neither group. Higher scores are associated with more problem behaviors. Research assistants who were trained and blinded to exposure status independently

interviewed the child and caretaker. Data were collected on a broad range of control variables known to influence childhood behavior and/or to be associated with prenatal alcohol exposure. These included perinatal factors of maternal age, education, cigarette, cocaine, and other substances of abuse and the gestational age of the baby. Postnatal factors studied included maternal psychopathology, continuing alcohol and drug use, family structure, socioeconomic status, children's whole blood lead level, and exposure to violence. Data were collected only from black women as there was inadequate representation of other racial groups. **STATISTICAL ANALYSES:** Statistical analyses were performed using the SPSS statistical package. Frequency distribution, cross-tabulation, odds ratio, and  $\chi^2$  tests were used for analyzing categorical data. Continuous data were analyzed using *t* tests, analyses of variance (ANOVAs) with posthoc tests, and regression analysis. **RESULTS:** Testing was available for 501 parent-children dyads. Almost one fourth of the women denied alcohol use during pregnancy. Low levels of alcohol use were reported in 63.8% and moderate/heavy use in 13% of pregnancies. Increasing prenatal alcohol exposure was associated with lower birth weight and gestational age, higher lead levels, higher maternal age, and lower education level, prenatal exposure to cocaine and smoking, custody changes, lower socioeconomic status, and paternal drinking and drug use at the time of pregnancy. Children with any prenatal alcohol exposure were more likely to have higher CBCL scores on Externalizing (Aggressive and Delinquent) and Internalizing (Anxious/Depressed and Withdrawn) syndrome scales and the Total Problem Score. The odds ratio of scoring in the clinical range for Delinquent behavior was 3.2 (1.3-7.6) in children with any prenatal exposure to alcohol compared with nonexposed controls. The threshold dose was evaluated with the 3 prenatal alcohol exposure groups. One-way ANOVA revealed a significant between group difference for Externalizing (Aggressive and Delinquent) and the Total Problem Score. (ABSTRACT TRUNCATED)

Sorantin E, Lindbichler F. [Nontraumatic injury (battered child)]. *Radiologie* 2002; 42(3):210-6. Abstract: The recognition of a battered child represents a challenge for all groups of adults dealing with children. Radiology plays a special role in this setting. By detection typical injuries, imaging is able to confirm the suspicion of a battered child. Recognition of those injuries on films, taken for other reasons, gives the caretaker an important hint, thus maybe preventing a fatal outcome for the child. One of the most important injury types is represented by the so called "shaken baby syndrome". The infant is held by the thorax and shaken. Thus causing a repetitive acceleration-deceleration trauma, which leads to the typical paravertebral rib fractures, intracranial bleeding and eye injuries. After shaking the child is thrown away, with subsequent injuries. The aim of this article

is the presentation of an overview regarding the radiology of the battered child. Typical examples will be shown.

Soto Mas F, Villalbi JR, Balcazar H, Valderrama Alberola J. [Smoking initiation: epidemiology, research, and behavioral sciences]. *An Esp Pediatr* 2002; 57(4):327-33.

Abstract: Becoming a regular smoker is a process that begins even before the first cigarette, and ends in lifelong physical and psychological dependence. Various psychological and behavioral factors contribute to this process. This article discusses smoking initiation from a comprehensive perspective, including the physiological and addictive effects of nicotine, and the personal and environmental factors that lead to smoking. Because smoking usually begins in adolescence, special emphasis is placed on this developmental stage and on the situations that encourage teenagers to smoke the first cigarette. Finally, this article analyzes the importance of the initiation process in the epidemiology and prevention of smoking. This approach may prove to be particularly useful to clinicians interested in interventions aimed to curb smoking.

Soulier J, Clappier E, Cayuela JM *et al.* HOXA genes are included in genetic and biologic networks defining human acute T-cell leukemia (T-ALL). *Blood* 2005; 106(1):274-86.

Abstract: Using a combination of molecular cytogenetic and large-scale expression analysis in human T-cell acute lymphoblastic leukemias (T-ALLs), we identified and characterized a new recurrent chromosomal translocation, targeting the major homeobox gene cluster HOXA and the TCRB locus. Real-time quantitative polymerase chain reaction (RQ-PCR) analysis showed that the expression of the whole HOXA gene cluster was dramatically dysregulated in the HOXA-rearranged cases, and also in MLL and CALM-AF10-related T-ALL cases, strongly suggesting that HOXA genes are oncogenic in these leukemias. Inclusion of HOXA-translocated cases in a general molecular portrait of 92 T-ALLs based on large-scale expression analysis shows that this rearrangement defines a new homogeneous subgroup, which shares common biologic networks with the TLX1- and TLX3-related cases. Because T-ALLs derive from T-cell progenitors, expression profiles of the distinct T-ALL subgroups were analyzed with respect to those of normal human thymic subpopulations. Inappropriate use or perturbation of specific molecular networks involved in thymic differentiation was detected. Moreover, we found a significant association between T-ALL oncogenic subgroups and ectopic expression of a limited set of

genes, including several developmental genes, namely HOXA, TLX1, TLX3, NKX3-1, SIX6, and TFAP2C. These data strongly support the view that the abnormal expression of developmental genes, including the prototypical homeobox genes HOXA, is critical in T-ALL oncogenesis.

Southam-Gerow MA, Weisz JR, Kendall PC. Youth with anxiety disorders in research and service clinics: examining client differences and similarities. *J Clin Child Adolesc Psychol* 2003; 32(3):375-85. Abstract: Compared 2 groups of children with anxiety disorders: those treated in a university-based research clinic (RC) and those treated in community-based service clinics (SCs). A widely endorsed goal in intervention research is to disseminate evidence-based treatments from RCs to SCs. Attaining this goal requires an understanding of the similarities and differences between clients in these 2 settings. Youth from SCs showed more comorbid externalizing diagnoses and externalizing problems and were more likely to come from low-income and single-parent families. On measures of internalizing symptomatology and diagnoses, youth from RCs were very similar to SC youth. To facilitate development of treatments with real-world applicability, we describe a model involving the testing of treatments in real-world settings. We also discuss limitations to this project.

Spak F, Allebeck P, Spak L, Thundal KL. [The Gothenburg study of women and alcohol: problems during childhood and adolescence important risk factors]. *Lakartidningen* 2001; 98(10):1109-14. Abstract: This is a part of longitudinal study concerning women and alcohol in Gothenburg. The aim was to find out more about risk factors for alcohol dependence and abuse (ADA) among women in the general population, as well as social conditions and life style among these women. Several indicators of dissatisfactory childhood conditions, and particularly sexual abuse before age 13, were related to ADA in adulthood. Early substance abuse, such as having been intoxicated before age 15 and having used narcotics before 18, was strongly related to future ADA. Our findings point to the need of paying attention to mental health problems in childhood and youth, and to prevent early use of alcohol and drugs.

Sparacino G, Milani S, Arslan E, Cobelli C. A Bayesian approach to estimate evoked potentials. *Comput Methods Programs Biomed* 2002; 68(3):233-48. Abstract: Several approaches, based on different assumptions and with various degree of theoretical sophistication and implementation complexity, have been developed for improving the measurement of evoked potentials (EP) performed by conventional averaging (CA). In many of these methods, one of the major challenges is the exploitation of a priori knowledge. In this paper, we present a new method

where the 2nd-order statistical information on the background EEG and on the unknown EP, necessary for the optimal filtering of each sweep in a Bayesian estimation framework, is, respectively, estimated from pre-stimulus data and obtained through a multiple integration of a white noise process model. The latter model is flexible (i.e. it can be employed for a large class of EP) and simple enough to be easily identifiable from the post-stimulus data thanks to a smoothing criterion. The mean EP is determined as the weighted average of the filtered sweeps, where each weight is inversely proportional to the expected value of the norm of the correspondent filter error, a quantity determinable thanks to the employment of the Bayesian approach. The performance of the new approach is shown on both simulated and real auditory EP. A signal-to-noise ratio enhancement is obtained that can allow the (possibly automatic) identification of peak latencies and amplitudes with less sweeps than those required by CA. For cochlear EP, the method also allows the audiology investigator to gather new and clinically important information. The possibility of handling single-sweep analysis with further development of the method is also addressed.

Spencer TJ, Biederman J, Wozniak J, Faraone SV, Wilens TE, Mick E. Parsing pediatric bipolar disorder from its associated comorbidity with the disruptive behavior disorders. *Biol Psychiatry* 2001; 49(12):1062-70. Abstract: The unique pattern of comorbidity found in pediatric mania greatly complicates accurate diagnosis, the course of the disorder, and its treatment. The pattern of comorbidity is unique by adult standards, especially its overlap with attention-deficit/hyperactivity disorder (ADHD), aggression, and conduct disorder. Clinically, symptoms of mania have been discounted as severe ADHD or ignored in the context of aggressive conduct disorder. This atypicality may lead to neglect of the mood component. The addition of high rates of additional disorders contributes to the severe morbidity, dysfunction, and incapacitation frequently observed in these children. A comprehensive approach to diagnostic evaluation is the keystone to establishing an effective treatment program because response to treatment differs with individual disorders. Recognition of the multiplicity of disorders guides therapeutic options in these often refractory conditions. What was previously considered refractory ADHD, oppositionality, aggression, and conduct disorder may respond after mood stabilization. We review these issues in this article.

- Spoth RL, Redmond C. Project Family prevention trials based in community-university partnerships: toward scaled-up preventive interventions. *Prev Sci* 2002; 3(3):203-21.  
 Abstract: Findings from Project Family are presented to illustrate how a partnership-based program of research on universal family- and youth-focused interventions is addressing a public health challenge. One aspect of this public health challenge is the high prevalence of youth problem behaviors and a second aspect concerns barriers to scaling-up empirically-supported preventive interventions designed to ameliorate those problem behaviors. Illustrative findings are presented within a conceptual framework for scaling-up preventive interventions to achieve greater public health impact. Three interrelated sets of research requirements and findings are addressed within this framework: (a) rigorously demonstrating intervention effectiveness; (b) attaining sufficient levels of intervention utilization in diverse general populations, requiring study of recruitment/retention strategies, cultural sensitivity, and economic viability; and (c) achieving implementation quality, involving investigation of adherence and dosage effects, along with theory-driven, intervention quality improvement. The paper concludes with discussion of the need for careful investigation of community-university partnership models as a key mechanism for large-scale implementation.

 GENERAL NOTE: KIE: KIE Bib: wrongful life  
 Abstract: The French government has given in to public pressure and overturned a controversial legal ruling which recognised the right of a disabled child to seek damages. Most notably, the ruling, widely described as establishing a child's right "not to be born", had provoked "outrage" amongst groups defending the rights of the disabled and led to a ban on prenatal scans by French gynaecologists. Once again, only parents will be able to seek damages but some people think the ruling has been misinterpreted.
- Springer-Kremser M, Leithner K, Fischer M, Loffler-Stastka H. Gender and perversion--what constitutes a "bad mother". *Arch Womens Ment Health* 2003; 6(2):109-14.  
 Abstract: BACKGROUND: There is a need for reconsidering the conceptualisations of female perverse behavior, especially in connection with motherhood. METHODS AND FINDINGS: Based on case material obtained through psychoanalytic psychotherapy with female patients from a psychosomatic gynecological outpatient clinic, the characteristics of the psychic structure of these patients who presented symptoms of deliberate self harm and of misusing and mistreating their children, are outlined. Another common trait is the embeddedness of their perverse behavior in a generational chain of transmission. Female patients who mistreat their children had been victims of traumatising experiences in their own biography, inflicted by their mothers and directed towards their bodies. DISCUSSION: Female perverse behavior, therefore, is fundamentally different from male perversion: the perverse act in women is aimed against themselves and/or their children. Currently used diagnostic statistical manuals lack categories to describe this symptomatology adequately. Further research is requested to understand a mother's perverse actions and thus develop treatment strategies, without marginalizing these patients.
- Spurrier NJ, Sawyer MG, Streiner D, Martin AJ, Kennedy D. New measure of parental asthma management for school-age children. *Pediatr Pulmonol* 2005; 40(3):241-50.  
 Abstract: A new parent-completed questionnaire to measure parental asthma management was developed. The new questionnaire takes a parental perspective, with content of items and scoring focusing on all behaviors considered important by parents and not just those considered appropriate by clinicians. Parents of 101 school-age children with a previous hospital admission with asthma completed the questionnaire during home visits. The questionnaire was based on five asthma scenarios. Parents were asked to indicate on a 6-point Likert scale how likely they would be to carry out a series of behaviors if the situations occurred. Two methods of scoring were used: scenario-based scoring, and factor-based scoring. Scenario-based subscale scores suggested that parent's level of activity was consistent across different situations. Factor analysis showed that the questionnaire had three dominant factors. The medical assessment subscale describes parent's level of activity in terms of seeking medical care, the external advice subscale describes parent's level of activity in terms of seeking assistance from knowledgeable others, and the home management subscale describes parents' approaches to monitoring and treating children at home. Alpha coefficients for scenario-based and factor-based subscales indicated good internal reliability (0.65-0.84 and 0.81-0.91, respectively). Test-retest reliability, 4 weeks apart, was also adequate (correlation coefficients of 0.75-0.87). This exploratory study describes the development of a new questionnaire, the Asthma Management Questionnaire (AMQ). The questionnaire has a unique parent focus, consistent with contemporary notions of

- patient-centered chronic-disease management.

- Stadler C, Schmeck K, Nowraty I, Muller WE, Poustka F. Platelet 5-HT uptake in boys with conduct disorder. *Neuropsychobiology* 2004; 50(3):244-51. Abstract: Dysregulation of serotonergic function has been found to be associated with aggression in animals, human adults and adolescents. However, studies with children have shown conflicting results. The objective of this study was to investigate whether the kinetic characteristics (Vmax and Km) of 5-HT uptake in platelets are different in children with the diagnosis of conduct disorder according to ICD-10 and healthy age-matched controls. In addition to the standardized assessment of general psychopathology, methods assessing narrowband aggressive symptoms (Child Behavior Checklist) and emotional reactivity to an experimentally induced provocation (Taylor's competitive reaction time task) were used in both groups. We found a trend for a lower mean Vmax of platelet 5-HT uptake in 14 conduct-disordered boys compared with healthy controls (n=15). If, however, 2 patients with a low degree of aggression and emotional reactivity were excluded, the difference became significant (mean=4.27, SD=3.49 in patients and mean=8.45, SD=4.63 in controls). A significant negative correlation was found between parent-rated aggression scores and Vmax ( $r=-0.41$ ,  $p < 0.05$ ,  $n=29$ ). These data suggest that dysfunction of 5-HT transport mechanisms might be associated with specific behavioral symptoms in conduct-disordered children.
- Stafford J, Lynn SJ. Cultural scripts, memories of childhood abuse, and multiple identities: a study of role-played enactments. *Int J Clin Exp Hypn* 2002; 50(1):67-85. Abstract: This study compared the reports of satanic, sexual, and physical abuse of persons instructed to role-play either dissociative identity disorder (DID) (n = 33), major depression (n = 33), or a college student who experienced minor adjustment problems ("normal") (n = 33) across a number of trials that included role-played hypnosis. As hypothesized, more of the participants who were asked to role-play DID reported at least one instance of satanic ritual abuse and sexual abuse compared with those who role-played depression or a college student with minor adjustment problems. DID role-players reported more incidents of sexual abuse and more severe physical and sexual abuse than did the major depression role-players. Further, the DID role-players differed from the normal role-players on all the measures of frequency and severity of physical and sexual abuse. Participants in all groups reported more frequent and severe incidents of physical abuse after role-played hypnosis than they did prior to it.
- Stahl C, Fritz N. Internet safety: adolescents' self-report. *J Adolesc Health* 2002; 31(1):7-10. Abstract: We examined the association between adolescents' unsafe experience online, types of Internet activity, and safety practices using a questionnaire returned by 213 private school students (seventh through tenth grades) in spring 1999. One-fourth of respondents reported unsafe experiences. Types of unsafe experience varied with gender, Internet activity, and identity sharing.

- Stalker CA, Russell BD, Teram E, Schachter CL. Providing dental care to survivors of childhood sexual abuse: treatment considerations for the practitioner. *J Am Dent Assoc* 2005; 136(9):1277-81. Abstract: BACKGROUND: Adults who experienced childhood sexual abuse frequently find dental treatment difficult to tolerate. Increased understanding of common long-term effects of this trauma may help dental professionals to respond more sensitively to patients who have experienced it. METHODS: The authors recruited 58 men and 19 women with self-reported histories of childhood sexual abuse from social agencies serving this population and interviewed the participants about their experiences with health care professionals, including dentists. The authors analyzed interview transcripts using the constant comparative method to identify main themes and patterns. RESULTS: Participants reported aspects of dental treatment that can be particularly difficult for them and offered ideas about how dental health professionals could make the experience more tolerable for them. The data analysis produced suggestions about how dentists might respond sensitively to patients who frequently cancel appointments, are distressed by certain body positions, need a sense of control and fear

judgment. The authors also report participants' thoughts about questions from dental practitioners regarding a history of childhood sexual abuse. **CONCLUSIONS:** Adults who report a history of childhood sexual abuse are more likely to experience dental treatment more positively when dental professionals have some understanding of the long-term effects of such abuse, including how it can affect dental treatment interactions. Such knowledge enables dental professionals to respond to their needs in a sensitive manner.

Staller KM, Nelson-Gardell D. "A burden in your heart": lessons of disclosure from female preadolescent and adolescent survivors of sexual abuse. *Child Abuse Negl* 2005; 29(12):1415-32. Abstract: **OBJECTIVES:** To enhance understanding of the sexual abuse disclosure process from the perspective of preteen and teenage survivors. To reconsider prominent models of the disclosure process in light of our findings. **METHODS:** We conducted a secondary analysis of data from four focus groups in which 34 preadolescent and adolescent female survivors of sexual abuse had been asked about their treatment experiences. Girls often recounted disclosing their victimization to others. Using the disclosure segment as our unit of analysis, we isolated 106 for study. During analysis, we wrote narrative summaries of each segment's significance, grouped these conceptually, and examined their interconnectedness. When synthesized, individual experiences of disclosing contributed to understanding the overall disclosure process. **RESULTS:** Three phases were identified: Self, where children come to understand victimization internally; Confidant Selection-Reaction, where they select a time, place, and person to tell and then weather that person's reaction (supportive or hostile); and Consequences (good and bad) that continued to inform their on-going strategies of telling. The actions and reactions of adults were significant and informed the girls' decisions. **CONCLUSIONS:** We advocate integrating existing theories and research into a model which views the disclosure process from the child's perspective and includes pre-disclosure and a post-initial public disclosure stages. The model conceptualizes disclosure as an iterative process in which children interact with adults and incorporate responses into their on-going decisions about telling (recant, deny, affirm, etc.). The combined model should recognize the concerns and position of adults as well as the perspective and logic of youth.

Stampi S, Ricci R, Ruffilli I, Zanetti F. Compulsory and recommended vaccination in Italy: evaluation of coverage and non-compliance between 1998-2002 in Northern Italy. *BMC Public Health* 2005; 5(1):42. Abstract: **BACKGROUND:** Since vaccinations are an effective prevention tool for maintaining the health of society, the monitoring of immunization coverage allows us to identify areas where disease outbreaks are

likely to occur, and possibly assist us in predicting future outbreaks. The aim of this study is the investigation of the coverage achieved for compulsory (diphtheria, tetanus, polio, hepatitis B,) and recommended (pertussis, Haemophilus influenzae, measles-mumps-rubella) vaccinations between 1998 and 2002 in the municipality of Bologna and the identification of the subjects not complying with compulsory and recommended vaccinations. **METHODS:** The statistics regarding vaccinal coverage were elaborated from the data supplied by the Bologna vaccinal registration system (1998-2000) and the IPV4 program (2001-2002). To calculate the coverage for compulsory vaccinations and cases of non-compliance reference was made to the protocol drawn up by the Emilia Romagna Regional Administration. The reasons for non-compliance were divided into various categories. **RESULTS:** In Bologna the levels of immunization for the four compulsory vaccinations are satisfactory: over 95% children completed the vaccinal cycle, receiving the booster for anti-polio foreseen in their 3rd year and for anti-diphtheria, tetanus, pertussis at 6 years. The frequency of subjects with total non-compliance (i.e. those who have not begun any compulsory vaccinations by the age of one year) is generally higher in Bologna than in the region, with a slight increase in 2002 (2.52% and 1.06% in the city and the region respectively). The frequency of the anti-measles vaccination is higher than that of mumps and rubella, which means that the single vaccine, as opposed to the combined MMR (measles-mumps-rubella) was still being used in the period in question. The most common reason for non compliance is objection of parents and is probably due to reduction of certain diseases or anxiety about the possible risks. **CONCLUSION:** In Bologna the frequency of children aged 12 and 24 months who have achieved compulsory vaccination varied, in 2002, between 95% and 98%. As regards recommended vaccinations the percentage of coverage against Haemophilus influenzae is 93.3%, while the levels for measles, mumps and pertussis range from 84% to approx. 92%. Although these percentages are higher if compared to those obtained by other Italian regions, every effort should be made to strengthen the aspects that lead to a successful vaccinal strategy.

Stanger C, Dumenci L, Kamon J, Burstein M. Parenting and children's externalizing problems in substance-abusing families. *J Clin Child Adolesc Psychol* 2004; 33(3):590-600.

Abstract: This study tested associations in path models among positive and negative parenting and children's rule-breaking behavior, aggressive and oppositional behavior, and attention problems for families with a drug-dependent parent. A structural model tested relations between parenting and children's externalizing problems for 251 families with 399 children between the ages of 6 and 18, controlling for nonindependence of ratings at the family level. The model also tested

potential moderators, including child age, gender, and ethnicity (White vs. other), and caregiver gender (families with a female substance-abusing caregiver vs. families with a male substance-abusing caregiver). Results indicated that caregiver ratings of monitoring predicted rule-breaking behavior and use of inconsistent discipline predicted ratings of all 3 externalizing syndromes, after controlling parenting and externalizing problems for the effects of the moderators and after controlling significant relations among types of parenting and types of externalizing problems.

Stanger C, Kamon J, Dumenci L *et al.* Predictors of internalizing and externalizing problems among children of cocaine and opiate dependent parents. *Drug Alcohol Depend* 2002; 66(2):199-212. Abstract: We tested associations in structural models among parent individual problems (severity of drug problems, medical problems, psychiatric symptoms), family problems, and children's internalizing and externalizing problems. Results were compared for cocaine versus opiate dependent parents, mothers versus fathers, boys versus girls, and older versus younger children. Cocaine and opiate dependent parents in treatment (N=211) were interviewed about their substance use, psychiatric symptoms, and interpersonal problems and completed a measure of family problems. Parents also rated children's internalizing and externalizing problems. In structural models controlling for the significant correlations between parent and family problems and between children's internalizing and externalizing problems, family problems but not individual parent problems predicted children's internalizing and externalizing symptoms. Models were similar across all groups compared with the exception of parent gender, with significant relations between parent and family problems for mothers but not for fathers. In addition, older girls were more deviant relative to their same-age and gender peers than the younger girls and boys. These results suggest that the personal problems of drug dependent mothers may influence children's problems indirectly by increasing family problems. For drug dependent fathers, family problems were an independent predictor of children's problems.

Stankaitis JA, Brill HR, Walker DM. Reduction in neonatal intensive care unit admission rates in a Medicaid managed care program. *Am J Manag Care* 2005; 11(3):166-72. Abstract: BACKGROUND: Neonatal intensive care unit admission rates are an important birth outcome indicator for Medicaid managed care organizations. OBJECTIVES: To reduce neonatal intensive care unit admission rates by at least 15% and to maintain that reduction through implementation of a quality improvement program. STUDY DESIGN: The organization performed a longitudinal population-based review of its birth outcomes from 1997 through

2003, focusing on neonatal intensive care unit admission rates. The return-on-investment evaluation reflected attributable incremental program costs and resultant savings. METHODS: Interventions included enhanced identification and stratification of high-risk women with the use of a health risk assessment form; outreach through nursing care coordination offering home visits, transportation, support services, social work services, and connection with other community-based organizations; and implementation of a strong informatics structure. RESULTS: Neonatal intensive care unit admission rates decreased from 107.6 per 1000 births in 1998 to 56.7 per 1000 births in 2003. The return on investment from the incremental program enhancements was just over dollars 2 per dollars 1 expended. CONCLUSION: A program that identifies its high-risk pregnant enrollees in a timely fashion, provides outreach using a strong nursing care coordination and social work emphasis, and has an enhanced informatics structure can significantly affect birth outcomes for a Medicaid managed care population.

Stanton B, Li X, Cottrell L, Kaljee L. Early initiation of sex, drug-related risk behaviors, and sensation-seeking among urban, low-income African-American adolescents. *J Natl Med Assoc* 2001; 93(4):129-38. Abstract: The purpose of this study was to examine the relationship of early initiation of sex, drug-use, drug-trafficking, and sensation-seeking among urban, African-American adolescents. A longitudinal follow-up of 383 youth ages 9 to 15 years at baseline over four years with serial risk-assessments was used. Sexual experience and several drug-related risk behaviors increased significantly during the four-year study interval. Sensation-seeking scores were higher after the baseline assessment among youth reporting tobacco, alcohol, and marijuana use and were higher, both at baseline and through several follow-up assessments, among youth reporting drug-selling and sexual activity. At baseline, the correlations among drug-related risk behaviors were all strong, except those between initiation of sex and drug-related risk behaviors. However, over time, early initiators of sex were significantly more likely to report involvement in substance use and drug-delivery/sales than were late initiators. Youth reporting repeated involvement in drug-related activities were more likely to report intensive sexual involvement than they were to report experimental sex or no sex. Sensation-seeking scores were lower among youth reporting no involvement in risk behaviors. However, scores did not differ between youth exhibiting experimental behavior compared to youth demonstrating repeated risk involvement. These results support the need for alternative experiences for youth exhibiting high levels of sensation-seeking and the need for early drug/sexual risk prevention programs.

Starkey F, Moore L, Campbell R, Sidaway M, Bloor M.

Rationale, design and conduct of a comprehensive evaluation of a school-based peer-led anti-smoking intervention in the UK: the ASSIST cluster randomised trial. *BMC Public Health* 2005; 5(1):43. Notes: CORPORATE NAME: ASSIST Abstract: BACKGROUND: To date, no school-based intervention has been proven to be effective in preventing adolescent smoking, despite continuing concern about smoking levels amongst young people in the United Kingdom. Although formal teacher-led smoking prevention interventions are considered unlikely to be effective, peer-led approaches to reducing smoking have been proposed as potentially valuable. METHODS/DESIGN: ASSIST (A Stop Smoking in Schools Trial) is a comprehensive, large-scale evaluation to rigorously test whether peer supporters in Year 8 (age 11-12) can be recruited and trained to effect a reduction in smoking uptake among their fellow students. The evaluation is employing a cluster randomised controlled trial (RCT) design with secondary school as the unit of randomisation, and is being undertaken in 59 schools in South East Wales and the West of England. Embedded within the trial are an economic evaluation of the intervention costs, a process evaluation to provide detailed information on how the intervention was delivered and received, and an analysis of social networks to consider whether such a peer group intervention could work amongst schoolchildren in this age group. Schools were randomised to either continue with normal smoking education (n = 29 schools, 5562 students), or to do so and additionally receive the ASSIST intervention (n = 30 schools, 5481 students). No schools withdrew once the trial had started, and the intervention was successfully implemented in all 30 schools, with excellent participation rates from the peer supporters. The primary outcome is regular (weekly) smoking, validated by salivary cotinine, and this outcome has been obtained for 94.4%, 91.0% and 95.6% of eligible students at baseline, immediate post-intervention, and one-year follow-up respectively. DISCUSSION: Comprehensive evaluations of complex public health interventions of this scale and nature are rare in the United Kingdom. This paper demonstrates the feasibility of conducting cluster RCTs of complex public health interventions in schools, and how the rigour of such designs can be maximised both by thorough implementation of the protocol and by broadening the scope of questions addressed in the trial by including additional evaluative components.

Starkuviene S, Zaborskis A. Links between accidents and lifestyle factors among Lithuanian schoolchildren. *Medicina (Kaunas)* 2005; 41(1):73-80. Abstract: The aim of the study was to evaluate associations of some lifestyle factors with injuries among schoolchildren. Analysis was performed using data from the survey conducted in 2002 according to the methods of World Health Organization Cross-National Study on Health Behavior in School-Aged

Children (HBSC). Using stratified random sampling, the representative sample of 5645 schoolchildren aged 11, 13, and 15 years from 104 schools of Lithuania was drawn and surveyed. Associations between potential risk factors and injuries among schoolchildren were evaluated calculating odds ratio and its 95% confidence intervals. For the evaluation of the impact of explanatory variables on analyzed event, logistic regression analysis was performed. Behavioral, psychological, and social integration factors were associated with the risk to sustain injuries among school-aged children. The impact of these factors varied within subgroups of schoolchildren by grade and sex. The most significant factors were: risk-taking behavior (smoking, alcohol and drug consumption, premature sexual activity), frequent participation in sport activities, involvement in physical fight, longer time spent away from home with friends, experienced bullying, poor self-assessed health and academic achievement, unhappiness, feeling unsafe at school, and high suicidal risk. Analysis failed to identify an expected association between lower socio-economic status and risk for injury. Integrated approach to injury etiology is essential in planning injury prevention and safety promotion activities among schoolchildren, paying particular attention to lifestyle factors, which can have the potential influence on risk to sustain injuries.

Stasevic I, Ropac D, Lucev O. Association of stress and delinquency in children and adolescents. *Coll Antropol* 2005; 29(1):27-32. Abstract: The aim of investigation was to assess the impact of subjective stress exposure on delinquent behaviour in children and adolescents. The study included 174 young male delinquents, selected by the method of stratified systematic (random) sample and divided into three age groups of <14, 14-17, and 18-21 years. General data, data on the type of criminal offence, and data on the type of deviant behaviour were collected. A standardised scale of subjective stress was used to allow for comparison of the results obtained in the study with those reported elsewhere. Analysis of variance, chi2-test and factor analysis were used on data processing. A majority of study subjects (55.2%) committed one criminal offence. The criminal offence structure was predominated by proprietary violation (66.7%). Common forms of deviant behaviour included shirking school duties (55.2%), and aggressive behaviour at school (31.0%), in public (29.5%) and in the family (23.6). Parental distrust and punishment (abuse) of the child were identified as the major sources of subjective stress. Youngest subjects significantly differed from other age groups according to their experience of subjective stress described as punishment (abuse) ( $F = 22.1389$ ,  $p < 0.001$ ). They were considerably more vulnerable to this type of stress than older age groups. These sources of stress were found to positively correlate with the number of criminal offences committed. Among the sources of

stress, parents' distrust of the child significantly correlated with commitment of one criminal offence ( $F = 2.8618$ ,  $p < 0.05$ ), and child's punishment (abuse) with a higher number of criminal offences ( $F = 3.1539$ ,  $p < 0.05$ ). Criminal activity of children and adolescents is significantly associated with their history of stress exposure over the last two years of life. The higher the stress severity, the greater the rate of delinquency.

Statman D. The right to parenthood: an argument for a narrow interpretation. *Ethical Perspect* 2003; 10(3-4):224-35.

Notes: GENERAL NOTE: KIE: 23 refs. 34 fn. GENERAL NOTE: KIE: KIE Bib: reproduction; reproductive technologies

Abstract: The paper argues for two kinds of limitations on the right of parenthood. First, it claims that the right to parenthood does not entail a right to have as many children as one desires. This conclusion follows from the standard justifications for the right to parenthood, none of which establishes the need to grant special protection to having as many children as one desires. Second, with respect to the right to receive assistance from the state in IVF, it is suggested that the state should also be allowed to take non-medical considerations into account in determining whether or not an applicant is entitled to this service, particularly in cases where the applicant seems to lack mothering ability.

Steele H. Unrelenting catastrophic trauma within the family: when every secure base is abusive. *Attach Hum Dev* 2003; 5(4):353-66; discussion 409-14.

Abstract: This paper will present illustrations from Adult Attachment Interviews conducted with adult female survivors of chronic ritual abuse in their family of origin. A model of multiple personality disorder informed by the Adult Attachment Interview coding and classification system will be presented. A range of victim, perpetrator and bystander personalities may be identified in the same interview, indeed in the same speaker. For the speaker who believes herself to be one of a number of co-existing personalities, integration and coherence means death of a loved one, indeed death of the sense of self. Possibilities of re-birth into a single integrated self are posited.

Steele RG, Anderson B, Rindel B *et al.* Adherence to antiretroviral therapy among HIV-positive children: examination of the role of caregiver health beliefs. *AIDS Care* 2001; 13(5):617-29.

Abstract: This study examined the association between two components of the Health Belief Model (perceived vulnerability and barriers) and adherence to antiretroviral therapy (ART) among children who are HIV-infected. The parents/caregivers of 30 children (mean age = 5.21,  $SD = 3.18$ ) who were HIV-infected and who were on active ART were surveyed to assess current methods of adherence assessment and

educational efforts within the institution. All participants (except one) were African American and reported low monthly family incomes ( $M = \$869.45$ ,  $SD = \$832.63$ ). Assessment instruments included measures of perceived vulnerability, caregiver-reported adherence and perceived barriers, and objective measures of adherence (clinical pill count; electronic measurement). The results failed to demonstrate a significant relationship between parental perceived vulnerability, perceived barriers and adherence to antiretroviral medications. Methods of assessing adherence provided significantly discrepant estimates of adherence. Results are discussed in terms of implications for patient care and for future research in this area. The addition of behavioural and motivational components to traditional educational approaches may positively impact treatment results.

Steen K, Hunskaar S. Gender and physical violence. *Soc Sci Med* 2004; 59(3):567-71.

Abstract: This study examines incidents of physical violence in relation to the sex of both assault victim and attacker. A survey of all assault victims attending an urban accident and emergency department (AED) in Norway during a 2-year period was carried out. All the assault victims were interviewed using a structured questionnaire administered by the attending physician as part of the initial consultation at the AED. During this interview, information about the victims, the attackers and the assaults was collected from the victims. Information on the sex, age, alcohol state of victims, and any referral to hospitals and specialists, was collected from the victim's medical notes at the AED. The severity of the victim's injuries was rated retrospectively using Abbreviated Injury Scale (AIS) and Shepherd's Injury Severity Scale for rating of injuries of assault. A total of 1234 men (74%) were attacked by other men, 354 women (21%) were attacked by men, 33 men (2%) by women, and 59 women (4%) by other women. The characteristics of the assaults carried out amongst female victim-female attacker and male victim-male attacker groups had many similarities. The same was found for the female victim-male attacker and male victim-female attacker groups. We conclude that changes in the traditional behaviour associated with women and men in relation to physical violence may be taking place.

Steen K, Hunskaar S. Violence: a prospective study of police and health care registrations in an urban community in Norway. *Med Sci Law* 2001; 41(4):337-41.

Steen K, Hunskaar S. Violence in an urban community from the perspective of an accident and emergency department: a two-year prospective study. *Med Sci Monit* 2004; 10(2):CR75-9.

Abstract: BACKGROUND: Information about violence in a given community is usually based on crime statistics. The aim of this study was to explore

violence in an urban community from the perspective of an accident and emergency department. **MATERIAL/METHODS:** All assault victims treated at the Bergen Accident and Emergency Department (AED) during a two-year period (1994-1996) were prospectively registered, and data were collected about the patients and the assault incidents. To assess the proportion of unrecognized assault victims treated at the AED, an anonymous questionnaire was sent to all adult patients (first-time consultations) who visited the AED during a ten-day period in 1997. **RESULTS:** 1803 assault victims were registered, 433 of whom (24%) were females. Most of the victims were young men assaulted at public locations, under the influence of alcohol, often by unknown attackers, and frequently feeling that the attack was unprovoked (and thus defined as street violence). Few victims of child abuse or elder abuse were identified. About 40% of the females were victims of domestic violence. Non-Norwegians, unemployed, and people living in economically deprived areas of the community were over represented. A minority of the assault victims wanted to press legal charges. From the postal survey (n=1264, response rate 43%) few unrecognized victims of violence could be identified among our patients. **CONCLUSIONS:** An accident and emergency department registration of violence victims will mostly identify male victims of street violence.

Stein JA, Leslie MB, Nyamathi A. Relative contributions of parent substance use and childhood maltreatment to chronic homelessness, depression, and substance abuse problems among homeless women: mediating roles of self-esteem and abuse in adulthood. *Child Abuse Negl* 2002; 26(10):1011-27.  
 Abstract: **OBJECTIVE:** This study, using latent variable methodology, explores simultaneously the relative effects of childhood abuse and early parental substance abuse on later chronic homelessness, depression, and substance abuse problems in a sample of homeless women. We also examine whether self-esteem and recent violence can serve as mediators between the childhood predictors and the dysfunctional outcomes. **METHOD:** The sample consists of 581 homeless women residing in shelters or sober living centers in Los Angeles (54% African-American, 23% Latina, 22% White, mean age=33.5 years). Multiple-indicator latent variables served as predictors and outcomes in structural models. Childhood abuse was indicated by sexual, physical, and verbal abuse. **RESULTS:** Childhood abuse directly predicted later physical abuse, chronic homelessness, depression, and less self-esteem. Parent substance use directly predicted later substance use problems among the women. Recent physical abuse predicted chronic homelessness, depression, and substance use problems. Greater self-esteem predicted less depression and fewer substance use problems. Childhood abuse also had significant indirect effects on depression, chronic homelessness, and drug and alcohol problems mediated

through later physical abuse and self-esteem. **CONCLUSIONS:** Although there was a strong relationship between childhood abuse and parent drug use, childhood abuse was the more pervasive and devastating predictor of dysfunctional outcomes. Childhood abuse predicted a wider range of problems including lower self-esteem, more victimization, more depression, and chronic homelessness, and indirectly predicted drug and alcohol problems. The mediating roles of recent physical abuse and self-esteem suggest salient leverage points for change through empowerment training and self-esteem enhancement in homeless women.

Steinhausen HC, Willms J, Metzke CW, Spohr HL. Behavioural phenotype in foetal alcohol syndrome and foetal alcohol effects. *Dev Med Child Neurol* 2003; 45(3):179-82.

Abstract: A sample of 12 children (seven males, five females; mean age 6 years 7 months, SD 2 years 6 months, range 2 years 4 months to 12 years 1 month) with moderate-to-severe foetal alcohol syndrome (FAS) and another sample of 26 children (12 males, 14 females; mean age of 6 years 2 months SD 2 years 10 months, range 2 years 6 months to 12 years 8 months) with mild FAS or foetal alcohol effects (FAE) as well as a sample of 15 age- and sex-matched control children with unspecific intellectual disability were compared using the Developmental Behaviour Checklist (DBC). There were significant differences (p=0.01) between the groups on five of six subscales of the DBC with controls scoring lower on the disruptive, self-absorbed, anxiety, antisocial behaviour, and communication disturbance scales. The DBC profiles of the two foetal alcohol exposed groups did not differ from each other. It is concluded that quantitative behaviour measurement provides insights into specific behavioural phenotypes of FAS/FAE.

Steliarova-Foucher E, Stiller C, Kaatsch P *et al.* Geographical patterns and time trends of cancer incidence and survival among children and adolescents in Europe since the 1970s (the ACCISproject): an epidemiological study. *Lancet* 2004; 364(9451):2097-105.

Abstract: **BACKGROUND:** Cancer is rare before age 20 years. We aimed to use the European database of

childhood and adolescent cancer cases, within the Automated Childhood Cancer Information System project, to estimate patterns and trends of incidence and survival within Europe. METHODS: Comparable, high-quality data from 63 European population-based cancer registries consisted of 113000 tumours in children and 18243 in adolescents diagnosed in 1970-99. Incidence rates and survival were compared by region (east vs west), period, and malignant disease. FINDINGS: In the 1990s, age-standardised incidence rates were 140 per million for children (0-14 years) and 157 per million for ages 0-19 years. Over the three decades, overall incidence increased by 1.0% per year ( $p < 0.0001$ ) in children (increases for most tumour types), and by 1.5% ( $p < 0.0001$ ) in adolescents (15-19 years; notable increases were recorded for carcinomas, lymphomas, and germ-cell tumours). Overall 5-year survival for children in the 1990s was 64% in the east and 75% in the west, with differences between regions for virtually all tumour groups; 5-year survival was much the same in adolescents. Survival has improved dramatically since the 1970s in children and adolescents, more so in the west than in the east. INTERPRETATION: Our results are clear evidence of an increase of cancer incidence in childhood and adolescence during the past decades, and of an acceleration of this trend. Geographical and temporal patterns suggest areas for further study into causes of these neoplasms, as well as providing an indicator of progress of public-health policy in Europe.

Sten E, Hansen TK, Stahl Skov P *et al.* Cross-reactivity to eel, eelpout and ocean pout in codfish-allergic patients. *Allergy* 2004; 59(11):1173-80. Abstract: Fish allergy is one of the most common food allergies in both children and adults and patients with allergic reactions to one fish species have in many cases been given the advice to avoid all fish, without further evaluation. The possible common reactivity between different fish species is not well studied. Because of this and a possible exploitation of fish species hitherto not much used in the Scandinavian diet ocean pout, eelpout and eel were evaluated. We examined the serological and biological cross-reactivity of these species in double-blind challenged-confirmed codfish-allergic patients using CAP, Maxisorp-radio allergosorbent test (RAST) inhibition, western blot, skin prick test (SPT) and histamine release (HR). All 18 codfish allergic patients had specific IgE to ocean pout, eelpout and eel determined by Maxisorp-RAST. All four fish species could induce basophil HR using blood from 16 of 18 patients and all patients tested reacted in SPT. This study demonstrates that patients with a verified clinical allergy to codfish in a high frequency express biological cross-reactivity to other fish species. By RAST inhibition this common reactivity was shown to be a true cross-reactivity.

Stephenson MT, Quick BL. Parent ads in the National Youth Anti-Drug Media Campaign. *J Health Commun* 2005; 10(8):701-10.

Abstract: The National Youth Anti-Drug Media Campaign aims not only to reduce drug use by teens and preteens, but also to arm parents with knowledge about specific parenting practices known to reduce the risk of teen drug use. Among the documented successes of the campaign to date was a small, but direct effect on some parenting practices, including parent-child discussions about drug use. To reach a deeper understanding about the substance of the parental ads, we content analyzed the message strategies employed in the campaign's parent ads over the inaugural 5 years of the campaign. Each ad was coded for its major theme, minor subtheme, and featured drug. Among seven possible major themes, the parental anti-drug ads largely featured four: enhance the risk of their child's drug use, encourage monitoring practices, promote parent-child discussions about drug use, or advocate positive involvement behaviors. Moreover, most parental messages addressed marijuana use or addressed drug use in general. Marijuana and inhalant ads largely were risk based, while general drug messages focused on monitoring, parent-child discussions or positive involvement practices.

Stephenson MT, Quick BL, Atkinson J, Tschida DA. Authoritative parenting and drug-prevention practices: implications for antidrug ads for parents. *Health Commun* 2005; 17(3):301-21.

Abstract: This research employed the theory of reasoned action to investigate the role of authoritative parenting in 3 drug-prevention behaviors: (a) parental monitoring, (b) parent-child discussions, and (c) awareness of the child's environment. A phone survey of 158 parents of adolescents in 7th, 9th, and 11th grades revealed that authoritative parenting was correlated with parenting practices that reduce the likelihood of adolescent drug use, including discussing family rules about drugs, discussing strategies to avoid drugs, discussing those in trouble with drugs, parental monitoring, knowing the child's plans for the coming day, and personally knowing the child's friends well. Additionally, authoritative parenting moderated the attitude-behavioral intention relation for parental monitoring and awareness of the child's environment, with the weakest relation detected for low-authoritative parents. The utility of these findings in helping design and target antidrug messages for parents more effectively is discussed.

Sterk CE, Klein H, Elifson KW. Perceived condom use self-efficacy among at-risk women. *AIDS Behav* 2003; 7(2):175-82.

Abstract: The objectives of this study are to assess the confidence in their ability to use condoms among at-risk women and identify predictors for the women's condom use self-efficacy. Structured interviews were

conducted with 250 adult women in Atlanta, Georgia, between August 1997 and August 2000. Overall, the women reported feeling moderately to moderately-strongly confident in their ability to use condoms consistently. Multivariate analysis showed women with higher condom use self-efficacy were significantly younger, experienced childhood neglect, had higher self-esteem, communicated better with their sex partner, and had fewer drug problems. Findings suggest the importance of addressing condom use self-efficacy in HIV risk reduction programs with a specific focus on women and the need to be attuned to tailored needs for specific subgroups such as older women or women who encountered childhood neglect.

Stern JM. Traumatic brain injury: an effect and cause of domestic violence and child abuse. *Curr Neurol Neurosci Rep* 2004; 4(3):179-81.

Sternberg KJ, Knutson JF, Lamb ME, Baradaran LP, Nolan CM, Flanzer S. The child maltreatment log: a computer-based program for describing research samples. *Child Maltreat* 2004; 9(1):30-48. Abstract: The Child Maltreatment Log (CML) is a computer-based program designed to record information about children's maltreatment experiences and associated life events. Addressing concerns posed by scientific panels and grant review panels, the CML was designed to improve upon existing instruments to facilitate collaboration among researchers interested in maltreatment. The CML encourages researchers to collect information from multiple sources and informants concerning children's maltreatment experiences. Rather than classifying types of maltreatment a priori, the CML allows researchers to describe children's experiences using objective descriptors pertaining to potential acts of abuse, potential perpetrators, frequency, onset, consequential injuries, and treatment. The CML can be downloaded by interested agencies and groups without charge.

Sterzer P, Stadler C, Krebs A, Kleinschmidt A, Poustka F. Abnormal neural responses to emotional visual stimuli in adolescents with conduct disorder. *Biol Psychiatry* 2005; 57(1):7-15. Abstract: BACKGROUND: It is widely held that aggression and antisocial behavior arise as a consequence of a deficiency in responding to emotional cues in the social environment. We asked whether neural responses evoked by affect-laden pictures would be abnormal in adolescents with conduct disorder (CD). METHODS: Functional magnetic resonance imaging during passive viewing of pictures with neutral or strong negative affective valence was performed in 13 male adolescents with severe CD aged 9 to 15 years and in 14 healthy age-matched control subjects. RESULTS: Main effects for negative-neutral affective valence included activations in the amygdala and hippocampus, ventral extrastriate visual cortex,

and intraparietal sulcus bilaterally. There was a significant group-by-condition interaction in the right dorsal anterior cingulate cortex that was due to a pronounced deactivation in the patient group during viewing of negative pictures. When correcting for anxiety and depressive symptoms, we additionally found a reduced responsiveness of the left amygdala to negative pictures in patients compared with control subjects. CONCLUSIONS: We suggest that these findings reflect an impairment of both the recognition of emotional stimuli and the cognitive control of emotional behavior in patients with CD, resulting in a propensity for aggressive behavior.

Stevens MC, Kaplan RF, Hesselbrock VM. Executive-cognitive functioning in the development of antisocial personality disorder. *Addict Behav* 2003; 28(2):285-300.

Abstract: The present study examined the association of cognitive-executive abilities to two risk factors for alcoholism, i.e., antisocial behaviors and a family history (FH+) of alcohol dependence. A sample of 91 right-handed, non-substance-dependent, young male adults recruited from the community were classified into three groups: (1) a control group of n=32 men with no history of DSM-III-R childhood conduct disorder (CD) or antisocial personality disorder (ASPD); (2) n=25 men who met criteria for a DSM-III-R childhood CD diagnosis, but did not meet diagnostic criteria for ASPD (i.e., CD/ASPD-); and (3) n=34 men who met DSM-III-R criteria for ASPD. They were further divided into those with and without a positive family history of alcoholism. A two-way (Antisocial Profile (3)x Family History of Alcoholism (2)) ANOVA was used to compare several neuropsychological measures of executive-cognitive functioning (ECF) ability. Verbal abstraction ability was found to be significantly lower in ASPD subjects compared with controls and CD-only subjects, inversely related to antisocial behavior severity (as measured by symptom count). CD-only and control subjects' abstraction ability were statistically indistinguishable. FH+ was associated with increased errors in planning performance on the Porteus Maze Test and diminished performance on Luria's simple alternate-tapping motor tasks. The effect was more pronounced when inhibition of prepotent motor planning was required. Results are consistent with previous work examining ECF ability in antisocial samples that find subtle differences in ECF ability compared to controls. The findings suggest that normal versus abnormal behavioral outcome for children with conduct problems may be influenced by cognitive ability profile, perhaps because of varying maturational processes.

Stevens TN, Ruggiero KJ, Kilpatrick DG, Resnick HS, Saunders BE. Variables differentiating singly and multiply victimized youth: results from the National Survey of Adolescents and implications for secondary prevention. *Child Maltreat* 2005; 10(3):211-23.

Abstract: The authors examined variables differentiating singly and multiply victimized youth with a national household probability sample of 4,023 adolescents. Youth endorsing one episode (i.e., one incident or series of repeat incidents) of sexual or physical assault were classified as singly victimized (n = 435). Multiply victimized youth were those who endorsed multiple discrete episodes of sexual or physical assault and both sexual and physical assault (n = 396). For boys, heightened risk of multiple victimization was associated with family alcohol problems, Native American race, and earlier age at assault onset. For girls, increased multiple victimization risk was associated with family alcohol problems, older current age, and several characteristics of the initial assault episode—earlier age at onset, acquaintance perpetrator, chronicity, perceived life threat, and injury. Findings imply that secondary prevention programs may be strengthened by broadening risk-reduction strategies to address a greater range of victimization experiences. Additional implications for secondary prevention are discussed.

Steves L, Blevins T. From tragedy to triumph: a segue to community building for children and families. *Child Welfare* 2005; 84(2):311-22.

Abstract: In 2000, more than 60 nonprofit agencies, health care providers, government officials, and community advocates in Tarrant County, Texas, came together to work for systemic change in the mental health care system. The coalition, known as the Mental Health Connection, began working toward a "No Wrong Door" approach to mental health services, which required aggressive coordination between federal, private, and nonprofit resources. The result is a five- to six-year plan for implementation of a new systems of care model for children with severe emotional disturbances and their families. The Mental Health Connection also focuses on legislative advocacy to bring about necessary policy changes at the local, state, and federal levels. Finally, the coalition focuses on developing sustainable revenue streams that will allow the new systems to remain in place once the group accomplishes the initial mission of the Mental Health Connection.

Stewart-Brown S. Legislation on smacking. *BMJ* 2004; 329(7476):1195-6.

Stewart-Brown S. Research in relation to equity: extending the agenda. *Pediatrics* 2003; 112(3 Part 2):763-5.

Abstract: An appreciation of the role of social and emotional well-being in determining health outcomes is important in advancing the equity agenda.(1) These aspects of health are adversely affected by inequity. They also are important as potential causal factors. Low levels of emotional and social well-being among the rich may be important in perpetuating health and social inequity. In the past, most research on inequity

has focused on the negative end of the continuum of emotional and social health (eg, child abuse, conduct disorder, mental illness, drug and alcohol abuse) and concentrated on the problems of the poor, not the rich. The prevalence of emotional and social well-being has not been well studied. At the other end of the spectrum, emotional and behavioral problems now are the most important cause of disability in childhood,(2) affecting between 10% and 20% of children.(3) In between these 2 extremes, some children are socially competent, are liked by their peers, are resilient in the face of problems, know their own minds, are kind to others, and are able to handle conflict in a way that leads to resolution. Others are prone to aggression and deceit, are ostracized by their peer group, and create conflict and distress. These children may have very low self-esteem. They often are manifestly unhappy and anxious and certainly make others unhappy and anxious. This group may not meet the Diagnostic and Statistical Manual of Mental Disorders-defined criteria for emotional and behavioral problems; teachers therefore may be more aware of them and their impact on others than physicians. As a result, teachers and educational psychologists have been at the forefront of developing interventions to help this group.

Stewart D, Sun J. How can we build resilience in primary school aged children? The importance of social support from adults and peers in family, school and community settings. *Asia Pac J Public Health* 2004; 16 Suppl:S37-41.

Abstract: This study examines the association between firstly, student resiliency and their perceptions of social support from parents/caregivers, teachers, and peers, and secondly, between student's perception of their general health status and their social support. A cross-sectional research project was designed and conducted in 2003 in an urban and remote area of Queensland, Australia. The study population comprised of 2580 students (Years three, five, and seven) across 20 primary schools. The main outcome measures were self-reported health status and resiliency behaviours. Independent variables included student perceptions of support from parents/caregivers, teachers, school peers, and prosocial groups. Students who perceived parents, teachers, and peers as supportive were more likely to have higher resiliency behaviour in communication and cooperation, self-esteem, empathy, help-seeking, goals and aspirations. Students who considered that their parents, peers at school and prosocial groups were supportive, were more likely to feel healthy. Findings suggest that providing adult and peer support to students at primary school age is a vital strategy in promoting student resiliency and general health for children of primary school age.

Stewart G, Ruggles R, Peacock J. The association of self-reported violence at home and health in primary school pupils in West London. *J Public Health (Oxf)* 2004; 26(1):19-23.

Abstract: **BACKGROUND:** The effects of violence upon young people are relatively poorly understood. In 2001 the London Borough of Ealing conducted a large-scale survey of primary school pupils, which included questions on levels of violence at home. The aim of this study was to measure the association of violence at home with measures of health, health care use and health-related behaviours in primary school pupils aged 9 and 11 in West London. **METHODS:** A total of 3007 pupils from 28 primary schools were given a self-complete health questionnaire; 2083 completed a question on violence at home. **RESULTS:** Pupils reporting violence were more likely to have needed medical attention in the last year. Violence was also associated with greater need of dental care, drinking and spending money on alcohol, spending money on cigarettes, not eating or drinking before school, less willingness to speak to parents and siblings about drugs, and less communication with teachers about puberty and growing up. Violence was positively associated with increased communication with relatives about puberty. **CONCLUSION:** Pupils who report violence at home are more likely to have more injuries, riskier health behaviours and less social support than those reporting no violence at home.

Stewart JL, Pyke-Grimm KA, Kelly KP. Parental treatment decision making in pediatric oncology. *Semin Oncol Nurs* 2005; 21(2):89-97; discussion 98-106. Abstract: **OBJECTIVE:** To review progress and future plans for a research program about parents' making treatment decisions for their children with cancer. **DATA SOURCES:** Theoretical papers, review articles, and research reports. **CONCLUSION:** Three important questions need to be addressed to achieve the goal of supporting parents in treatment decision making: 1) What factors predict a parent's preferred role in decision making? 2) What are the critical outcomes from parental decision making that nurses could help to improve? 3) Is it role choice, actual role assumed, or congruence between preferred and actual role in decision making that predicts decision outcomes for the parents? **IMPLICATIONS FOR NURSING PRACTICE:** Research-based responses to the remaining questions about parent treatment decision making will help nurses develop and test interventions designed to support parents in their decision making experiences.

Stewart M, Jackson D, Mannix J, Wilkes L, Lines K. Current state of knowledge on child-to-mother violence: a literature review. *Contemp Nurse* 2004-2005; 18(1-2):199-210. Abstract: Child-to-mother violence is a common aspect of family violence, and presents nurses and health workers with continuing challenges. Though noted in the literature as early as the 1950's, this phenomenon remains poorly understood. A number of reasons for the lack of research scrutiny are proposed, the most compelling being that child-to-mother violence has

been framed within the discourse of juvenile delinquency rather than family violence. Thus, unlike other forms of family violence, it has escaped close examination by health and welfare workers. A literature review was conducted to examine current knowledge of child-to-mother violence. Study of the literature reveals only partial understandings of this neglected aspect of family pathology. Directions for research to address these gaps in knowledge are drawn from the findings of this literature review.

Stoddard FJ, Saxe G. Ten-year research review of physical injuries. *J Am Acad Child Adolesc Psychiatry* 2001; 40(10):1128-45.

Abstract: **OBJECTIVE:** To review the past 10 years of research relevant to psychiatry on injuries in children and adolescents. **METHOD:** A literature search of databases for "wounds and injuries, excluding head injuries," was done with Medline and PsycINFO, yielding 589 and 299 citations, respectively. Further searching identified additional studies. **RESULTS:** Progress is occurring in prevention, pain management, acute care, psychiatric treatment, and outcomes. The emotional and behavioral effects of injuries contribute to morbidity and mortality. Psychiatric assessment, crisis intervention, psychotherapy, psychopharmacological treatment, and interventions for families are now priorities. Research offers new interventions for pain, delirium, posttraumatic stress disorder, depression, prior maltreatment, substance abuse, disruptive behavior, and end-of-life care. High-risk subgroups are infants, adolescents, maltreated children, suicide attempters, and substance abusers. Staff training improves quality of care and reduces staff stress. **CONCLUSIONS:** Despite the high priority that injuries receive in pediatric research and treatment, psychiatric aspects are neglected. There is a need for assessment and for planning of psychotherapeutic, psychopharmacological, and multimodal treatments, based on severity of injury, comorbid psychopathology, bodily location(s), and prognosis. Psychiatric collaboration with emergency, trauma, and rehabilitation teams enhances medical care. Research should focus on alleviating pain, early psychiatric case identification, and treatment of children, adolescents, and their families, to prevent further injuries and reduce disability.

Stoffels H, Ernst C. [Recall and pseudo-memory. On the yearning to be a trauma victim]. *Nervenarzt* 2002; 73(5):445-51.

Abstract: Memories are not called up from "storage"

but instead are constructed anew in each case. Although many experiments have proven that memories are visual and inaccurate, many psychotherapists still assume that memories which surface during therapy are realistic representations of facts. They do not take into account that reminiscences (pseudomemories) of events can be planted in the memory by the imagination or through behavioral pressure. In light of this, the question arises as to why some patients during therapy tend to invent in particular memories of traumatic early childhood experiences. The authors assume that certain suggestive elements come to bear with victimization. The advantage gained is of great importance and has many facets. The case of Wilkomirski proves that mystification of the ego via identification with victims is not only provoked in psychotherapeutic treatment but also is a means of gaining public attention and support. As concerns the therapeutic handling of actual emotional traumatization (whose pathogenic significance and long-term effects used to be underestimated), suggestive and autosuggestive processes play a large role. In this respect, modern trauma research and psychotherapy are faced with special challenges.

Stokes E, Gilbert-Palmer D, Skorga P, Young C, Persell D. Chemical agents of terrorism: preparing nurse practitioners. *Nurse Pract* 2004; 29(5):30-9; quiz 39-41.

Abstract: Nurse practitioners must exercise vigilant readiness to properly care for victims of chemical injuries. In this article, appropriate clinical management of each category of chemicals is addressed, including supportive and pharmacologic care. Triage decisions are explained and decontamination concerns are identified. Attention is directed at special populations such as children and the elderly.

Stokowski LA. Make every mother and child count--World Health Day. *Adv Neonatal Care* 2005; 5(3):124.

Stolt UG, Helgesson G, Liss PE, Svensson T, Ludvigsson J. Information and informed consent in a longitudinal screening involving children: a questionnaire survey. *Eur J Hum Genet* 2005; 13(3):376-83.

Abstract: This empirical study explores participants' perceptions of information and understanding of their children's and their own involvement in a longitudinal screening, the ABIS Study. ABIS (All Babies In Southeast Sweden) is a multicentre, longitudinal research screening for Type 1 diabetes and multifactorial diseases involving 17 005 children and their families. For this study, a random selection of mothers was made, using perinatal questionnaire serial numbers from the ABIS study. In total, 293 of these mothers completed an anonymous questionnaire (response rate 73.3%). Our findings from the

questionnaire indicate a marked difference between the reported satisfaction with and understanding of the information provided on the one hand and the significant lack of knowledge of some of the aims and methods of the ABIS screening on the other, namely concerning high-risk identification of involved children, potential prevention and future questionnaires. Two questions evoked by our results are: (1) what information is required for participants in longitudinal studies involving children? and (2) how do we ensure and sustain understanding, and thus in a prolonging, informed consent in these studies? This study underlines the importance of an increased understanding of the ethical issues that longitudinal research on children raise and the need to discuss how information and informed consent strategies should be analysed and designed in longitudinal studies.

Stone AL, Latimer WW. Adolescent substance use assessment: concordance between tools using self-administered and interview formats. *Subst Use Misuse* 2005; 40(12):1865-74.

Abstract: The present study evaluates the agreement between adolescent self-report of substance use frequencies obtained from a self-administered questionnaire vs. face-to-face interview formats. Participants were 108 adolescents (82 males, 26 females), aged 11 to 19 ( $M = 15.74$ ,  $SD = 1.17$ ), who were referred for a chemical dependence assessment between June of 1999 and June of 2000 in Minnesota. The adolescent battery included the self-administered Personal Experience Inventory and the face-to-face interviewer-administered Drug Use History Interview to assess substance use frequency. A urine sample was also collected to validate self-report of recent substance use. Bivariate correlations between adolescent self-report on the self-administered and interviewer-administered formats were strong for alcohol (average  $r = 0.72$ ) and marijuana (average  $r = 0.81$ ) use frequencies during the 3 months and 12 months preceding the baseline assessment. However, adolescents were generally more likely to report greater frequencies of alcohol and marijuana use during the interview-administered protocol when compared to the self-administered format. Study implications and limitations are discussed.

Stone NN. Hand-drumming to build community: the story of the Whittier Drum Project. *New Dir Youth Dev* 2005; (106):73-83, 6.

Abstract: Over the years, the author participated in drum circles and classes in Denver, Fort Collins, and Boulder, Colorado. He noticed that drumming made him feel grounded and at peace. Drumming is very accessible, not like playing the piano or violin. Simple rhythms can be taught to people with no drumming experience very quickly and an ensemble rhythm created with a group in one sitting. Drumming turned out to be a highly effective way to engage with young people not only to address their individual spirits but to

join with others to create a community.

Stoolmiller M. Synergistic interaction of child manageability problems and parent-discipline tactics in predicting future growth in externalizing behavior for boys. *Dev Psychol* 2001; 37(6):814-25.  
Abstract: Manageability problems during early childhood for boys were hypothesized to disrupt parental discipline practices. In turn, disrupted parental discipline practices were hypothesized to interact with manageability problems during late childhood to predict change in antisocial behavior during the transition from elementary to middle school. Results indicated that maternal retrospective perceptions of unmanageability predicted observed maternal discipline practices, even when maternal antisocial behavior and depressed mood and the disruptive and antisocial behavior of the boy were statistically controlled. Graphical analyses and latent class growth models indicated that level of temper tantrums interacted with maternal discipline in predicting change in teacher ratings of antisocial behavior. The nature of the interaction indicated that maternal discipline was a risk factor for growth in antisocial behavior only for boys with high levels of tantrums.

Stormshak EA, Comeau CA, Shepard SA. The relative contribution of sibling deviance and peer deviance in the prediction of substance use across middle childhood. *J Abnorm Child Psychol* 2004; 32(6):635-49.

Abstract: This study investigated the quality of sibling relationships and sibling deviancy in a sample of children at-risk for substance use and antisocial behavior. Based on a history of empirical and theoretical models suggesting strong associations between children's development in the context of relationships and the emergence of delinquency and drug use, this research extends previous efforts by including sibling relationships in this developmental model, linking siblings with later substance use. Sibling relationship quality as well as peer deviance were examined using a multirater, multimethod assessment procedure. We tested 3 constructs (deviancy, warmth, and conflict) related to sibling behavior. Only sibling deviance and peer deviance directly predicted substance use. When both sibling deviance and peer deviance were examined as predictors of changes in substance use over time, only

sibling deviance was significant. Implications for the development of substance use behavior in middle childhood are discussed.

Storvoll EE, Wichstrom L. Do the risk factors associated with conduct problems in adolescents vary according to gender? *J Adolesc* 2002; 25(2):183-202.  
Abstract: The present paper examines whether there are gender differences in the associations between conduct problems and risk factors such as family conditions, peer influence, leisure activities, school-related variables and pubertal timing. We analysed self-reported data collected as part of a large general population study of Norwegian adolescents (N=9342). On the basis of earlier studies, conduct problems were decomposed into three dimensions, labelled theft and vandalism, school opposition and covert behaviour. The first dimension includes different kinds of theft and vandalism, whereas the second includes school-related conduct problems of an overt aggressive kind. The last dimension reflects avoidance of arenas under adult control. Whether or not gender differences were detected depended on the aspect of conduct problems considered. The associations between risk factors and "theft and vandalism" and "school opposition" were stronger for boys than for girls. No gender differences were detected in the associations between and risk factors and "covert behaviour". Even though there were gender differences in the strength of these associations, the same risk factors seem to be relevant in explaining conduct problems for both gender groups.

Stover CS. Domestic violence research: what have we learned and where do we go from here? *J Interpers Violence* 2005; 20(4):448-54.  
Abstract: Domestic violence has been an intense area of study in recent decades. Early studies helped with the understanding of the nature of perpetration, the cycle of violence, and the effect of family violence on children. More recently, studies have focused on beginning to evaluate domestic violence interventions and their effects on recidivism. This article acknowledges the importance of what we have learned about the prevalence and impact of domestic violence and explores the need for more focused effort to pinpoint interventions that are effective with perpetrators and victims. Methodological issues relevant to past intervention studies are also discussed and future research directions are outlined.

Straetmans M, Schonbeck Y, Engel JA, Zielhuis GA. Meconium-stained amniotic fluid is not a risk factor for otitis media. *Eur Arch Otorhinolaryngol* 2003; 260(8):432-5.

Abstract: It has recently been hypothesised that large amounts of amniotic fluid cellular content (AFCC) in the middle ear may lead to chronic inflammation and predispose young children to recurrent middle ear infections. Because children born with meconium-

stained amniotic fluid (MSAF) have higher AFCC in the middle ear, we performed a retrospective cohort study to determine whether children born with MSAF had a higher risk of OM during infancy. Children born between May 1998 and April 2000 formed two groups based on the absence or presence of MSAF at birth as documented in the hospital birth records. In April 2002, home visits were made to take tympanometric measurements and administer a questionnaire on OM history and possible confounders. Logistic regression models were constructed to assess odds ratios (OR) as a measure of the effect of MSAF on OM and to adjust for potential confounders. There were no differences in the point prevalence of a type-B tympanogram at the home visit (OR 0.81; 95% confidence interval: 0.38-1.76). Also, no statistically significant association was found between the proportion of children with OM diagnosed in the 1st year of life (OR 0.86, 95% confidence interval: 0.27-2.73) and in the proportion of children that had ever been diagnosed with OM (OR 0.91, 95% confidence interval: 0.40-2.91). It can be concluded that children born with MSAF do not constitute a high-risk group for OM in early childhood. A long-term OM effect, especially in severe MSAF cases, cannot be excluded.

Strasburger VC. Adolescents, sex, and the media: ooooo, baby, baby-a Q & A. *Adolesc Med Clin* 2005; 16(2):269-88, vii.  
Abstract: The media arguably have become the leading sex educator for American children and adolescents. More than 80% of the top teen shows contain sexual content, and the average teen views nearly 14,000 sexual references on television alone. The gap between suggestive and responsible content on primetime television is narrowing, but only slowly. Parents and teachers need to recognize the power of the media to educate and begin incorporating principles of media literacy into existing sex education programs.

Stratman E, Melski J. Scald abuse. *Arch Dermatol* 2002; 138(3):318-20.

Strauch H, Wirth I, Taymoorian U, Geserick G. Kicking to death - forensic and criminological aspects. *Forensic Sci Int* 2001; 123(2-3):165-71.  
Abstract: A total of 36,274 forensic autopsies was performed in Berlin, between 1980 and 1987, including 152 cases (0.42%) in which death had been caused by blunt violence due to kicking. Data were collected on both victims and offenders, postmortem findings, causes of death and the way violence had been perpetrated. The greater part of victims and offenders had been males originating from lower social strata. Most of the victims and offenders had been in relationship with each other prior to the offence. Typical course of events: Victims and offenders, under influence of alcohol, became involved in a brawl, usually for trivial reasons, which soon led to physical

fighting. When the victim had been knocked to the ground, the offender started forceful kicking. Bleeding to death and head injury were frequent causes of death. More than 50% of all offences were committed by single offenders. The diagnosis of kicking to death can at best be derived from presence of boot traces leaving shaped injuries. The trace-generating boot can be identified as offending tool by means of comparative police investigation. In addition to evaluation of shoe sole profiles, there is other trace-relevant material that may be sampled from a suspected offender's footwear (skin cells, hair, blood, body tissue) and used to identify findings by DNA analysis. There may be injuries with visible patterns supporting suspicion of kicking and trampling, although conclusive confirmation can be obtained only by testimony by a witness or confession by the offender.

Strina A, Cairncross S, Barreto ML, Larrea C, Prado MS. Childhood diarrhea and observed hygiene behavior in Salvador, Brazil. *Am J Epidemiol* 2003; 157(11):1032-8.

Abstract: Brief biweekly home visits, made as part of a cohort study of diarrhea in young children under age 5 years that was carried out in Salvador, Brazil, in 1998-1999, were used as a low-cost way to collect structured observation data on domestic hygiene behavior. Fieldworkers were trained to check a list of 23 forms of hygienic or unhygienic behavior by the child or the child's caretaker, if any behaviors were seen during the visit. Children were grouped according to whether mainly unhygienic behavior or mainly hygienic behavior had been recorded. This permitted study of the determinants of hygiene behavior and of its role in the transmission or prevention of diarrheal disease. Observations were recorded on roughly one visit in 20. Households with adequate excreta disposal were significantly more likely to be in the "mainly hygienic" group. The prevalence of diarrhea among children for whom mainly unhygienic behavior was recorded was 2.2 times that among children in the "mainly hygienic" group. The relative risk for prevalence was 2.2 (95% confidence interval: 1.7, 2.8). The relative risk fell to 1.9 (95% confidence interval: 1.5, 2.5) after data were controlled for confounding, but the difference was still highly significant.

Strina A, Cairncross S, Prado MS, Teles CA, Barreto ML. Childhood diarrhoea symptoms, management and duration: observations from a longitudinal community study. *Trans R Soc Trop Med Hyg* 2005; 99(6):407-16.  
Abstract: This study examined the evolution and duration of diarrhoea episodes observed in a community setting, with regard to symptoms and carers' responses. The study group comprised 1156 children, aged 0-36 months, who were followed-up with twice-weekly home visits in 30 sampling areas in the city of Salvador, northeast Brazil. A total of 2403 diarrhoea episodes (mean duration: 2.9 days) were recorded. The number of soft/liquid motions per day

(3.6) did not vary significantly with duration, but other symptoms were more commonly reported in the longer episodes. However, when the data were analysed by day of the episode, rather than the episode's overall duration, the reported frequency of fever and vomiting declined significantly with time. During the course of an episode, rehydration, medication and care-seeking also showed a decline in frequency after the first or second week. As episodes continue, less rehydration and medical care are provided by carers, whereas they ought to be maintained because of the continued purging and cumulative effect of the symptoms. Since most cases of diarrhoea are managed at home, it is important to understand how to encourage better management of the longer episodes, which cause an increasing proportion of mortality in some countries.

Stritzke WG, Dandy J, Durkin K, Houghton S. Use of interactive voice response (IVR) technology in health research with children. *Behav Res Methods* 2005; 37(1):119-26.

Abstract: This article reports on the feasibility of using interactive voice response (IVR) technology to obtain daily reports of attitudes toward alcohol and tobacco use among children 9-13 years of age. Two studies were conducted. The first was an investigation of the use of IVR technology to obtain daily data from a sample of primary school children over a period of 8 weeks. The second was an extension of the research to a large sample of primary and secondary school children in urban and rural areas who provided daily data over a 4-week period. Retention and compliance rates comparable to those obtained with adults were evident in both studies, supporting the feasibility of this technology with children. The results are discussed in relation to the benefits of this methodology for health research, particularly for studies of sensitive topics conducted with children and adolescents.

Strong DR, Brown RA, Ramsey SE, Myers MG. Nicotine dependence measures among adolescents with psychiatric disorders: evaluating symptom expression as a function of dependence severity. *Nicotine Tob Res* 2003; 5(5):735-46.

Abstract: Using methods based in item response theory, we examined a structured interview assessment of Diagnostic and Statistical Manual of Mental Disorders, 4th edition (DSM-IV) nicotine dependence and the Modified Fagerstrom Tolerance Questionnaire (mFTQ) symptoms to explore the expression of particular symptoms as a function of level of nicotine involvement in a sample of 191 adolescents with psychiatric disorders. Despite our attempts to capture a broad range of smokers, 64% of teens were daily smokers and 68% met DSM-IV criteria for nicotine dependence. This paper describes the relative severity of DSM-IV and mFTQ items, as well as each item's ability to discriminate among individuals at various levels of nicotine involvement. Comparisons across measures revealed that the mFTQ was not particularly

sensitive to individual variation in DSM-IV symptom counts, suggesting the physiological components were not strongly related to the predominantly cognitive and behavioral components of the DSM-IV nicotine dependence syndrome. However, the mFTQ relative to the DSM-IV consistently showed stronger relationships to the immediate consequences of nicotine deprivation (urge, craving), supporting the conceptualization of the mFTQ as measuring nicotine exposure. These analyses provide us with some preliminary understanding of the severity of particular symptoms and the order in which symptoms are likely to be expressed across levels of nicotine dependence.

Struffert T, Grunwald I, Reith W. [Cranio-cerebral trauma in childhood]. *Radiologe* 2003; 43(11):967-76. Abstract: This article describes typical head injuries in infants and children. In comparison with adults there are distinct differences in the etiology of trauma and in the kind of reaction of the skull and brain. In infants and children there are three different types of trauma: birth trauma, accidental and non-accidental injury. The typical injuries in these three groups are described.

Stuhlmiller DF, Cudnik MT, Sundheim SM, Threlkeld MS, Collins TE Jr. Adequacy of online medical command communication and emergency medical services documentation of informed refusals. *Acad Emerg Med* 2005; 12(10):970-7.

Abstract: BACKGROUND: In the out-of-hospital setting, when emergency medical services (EMS) providers respond to a 9-1-1 call and encounter a patient who wishes to refuse medical treatment and/or transport to the hospital, the EMS providers must ensure the patient possesses medical decision-making capacity and obtain an informed refusal. In the city of Cleveland, Ohio, Cleveland EMS completes a nontransport worksheet that prompts the paramedics to evaluate specific patient characteristics that can influence medical decision-making capacity and then discuss the risks of refusing with the patient. Cleveland EMS then contacts an online medical command (OLMC) physician to authorize the refusal. OLMC calls are recorded for review. OBJECTIVES: To assess the ability of EMS to determine medical decision-making capacity and obtain an informed refusal of transport. METHODS: This study was a retrospective review of a cohort of recorded OLMC refusal calls and of the accompanying written documentation by Cleveland EMS. The completeness of the verbal communication between the paramedic and OLMC physician and the written documentation on the nontransport worksheet were measured as surrogate markers of the adequacy of determining medical decision-making capacity and obtaining an informed refusal. RESULTS: One hundred thirty-seven OLMC calls for patient-initiated refusals were reviewed. Vital signs and alertness/orientation were verbally communicated more than 83% of the time. The presence of head injury, presence of alcohol or drug

intoxication, and presence of hypoglycemia were verbally communicated less than 31% of the time. Verbal communication stating that the risks of refusing had been discussed with the patient occurred 44.5% of the time. The written documentation of the refusal encounter was more complete, exceeding 95% for vital signs and alertness/orientation, and exceeding 80% for the remaining patient characteristics. The rate of written documentation that the risks of refusing had been discussed with the patient was 48.7%. Discrepancies between the verbal and written paramedic reports were clinically insignificant. CONCLUSIONS: Paramedic and OLMC physician communication for patients refusing out-of-hospital medical treatment and/or transport is inadequate in the Cleveland EMS system. A written nontransport worksheet improves documentation of the refusal encounter but does not ensure that every patient who refuses possesses medical decision-making capacity and the capacity to provide an informed refusal.

Sturdy PM, Victor CR, Anderson HR *et al.* Psychological, social and health behaviour risk factors for deaths certified as asthma: a national case-control study. *Thorax* 2002; 57(12):1034-9. Notes: CORPORATE NAME: Mortality and Severe Morbidity Working Group of the National Asthma Task Force Abstract: BACKGROUND: Uncontrolled studies suggest that psychosocial factors and health behaviour may be important in asthma death. METHODS: A community based case-control study of 533 cases, comprising 78% of all asthma deaths under age 65 years and 533 hospital controls individually matched for age, district and asthma admission date corresponding to date of death was undertaken in seven regions of Britain (1994-98). Data were extracted blind from anonymised copies of primary care records for the previous 5 years and non-blind for the earlier period. RESULTS: 60% of cases and 63% of controls were female. The median age in both groups was 53. Cases had an earlier age of asthma onset, more chronic obstructive lung disease, and were more obese. 48% of cases and 42% of controls had a health behaviour problem; repeated non-attendance/poor inhaler technique was related to increased risk of death. Overall, 85% and 86%, respectively, had a psychosocial problem. Four psychosocial factors were associated with increased risk of death (psychosis, alcohol/drug abuse, financial/employment problems, learning difficulties) and two with reduced risk (anxiety/prescription of antidepressant drugs and sexual problems). While alcohol/drug abuse lost significance after adjustment for psychosis, other associations appeared independent of each other and of indicators of severity and co-morbidity. None of the remaining 13 factors including family problems, domestic abuse, bereavement, and social isolation were significantly related to risk of asthma death. CONCLUSION: There was an apparently high burden

of psychosocial problems in both cases and controls. The associations between health behaviour, psychosocial factors, and asthma death are varied and complex with a limited number of factors showing positive relationships.

Suarez-Orozco C, Todorova IL. The social worlds of immigrant youth. *New Dir Youth Dev* 2003; (100):15-24.

Abstract: This introductory chapter uses a detailed case study to illustrate the interconnection of multiple social influences on one particular youth's path of migration. It further identifies some of the major influences on immigrant youth development, including the stresses of migration, separations and reunifications, changing networks of relations, poverty and segregation, and identity formation.

Subkowski P. [Harry Potter--the trauma as a drive for psychic development]. *Prax Kinderpsychol Kinderpsychiatr* 2004; 53(10):738-53.

Abstract: The Harry Potter books are centered around the psychic development of a traumatised young boy starting from his internalised early experience of being loved by his mother to the sudden loss of both of his parents at the anal stage and the later cumulative traumatisation by being neglected and mistreated by his relatives up to the present times. By identifying with his father and other father replacements Harry Potter finally acquires self-assurance and wins new friends. Harry goes through different stages of initiation into the adult world with all its conflicts and rivalries but also friendships. He stands up to his fears and symptoms resulting from his early childhood traumata and thereby helps to encourage readers of all ages to handle their own conflicts. On the oedipal level Harry Potter finally has to deidealize his father and Dumbledore, but also their opponent the dark Lord Voldemort, who thereby becomes more human, understandable and in the long run probably defeatable. The reader can identify himself with Harry and/ or a wide range of other characters. He can recognize his own experiences in life and conflicts in the story and argue internally with the demonstrated conflict solving patterns on different levels. It is the skillfully displayed and logically constructed story of the psychic development of a child that is traumatised at an early age and the possibilities the reader has to identify selectively with the different characters that constitutes the attractiveness of the Harry Potter novels.

Suchman N, Mayes L, Conti J, Slade A, Rounsaville B. Rethinking parenting interventions for drug-dependent

mothers: from behavior management to fostering emotional bonds. *J Subst Abuse Treat* 2004; 27(3):179-85.

Abstract: Mothers who are physically and/or psychologically dependent upon alcohol and illicit drugs are at risk for a wide range of parenting deficits beginning when their children are infants and continuing as their children move through school-age and adolescent years. Behavioral parent training programs for drug-dependent mothers have had limited success in improving parent-child relationships or children's psychological adjustment. One reason behavioral parenting programs may have had limited success is the lack of attention to the emotional quality of the parent-child relationship. Research on attachment suggests that the emotional quality of mother-child relationships is an important predictor of children's psychological development through school-age and adolescent years. In this paper, we present a rationale and approach for developing attachment-based parenting interventions for drug-dependent mothers and report preliminary data on the feasibility of offering an attachment-based parenting intervention in an outpatient drug treatment program for women.

Suchman NE, McMahon TJ, Luthar SS. Interpersonal maladjustment as predictor of mothers' response to a relational parenting intervention. *J Subst Abuse Treat* 2004; 27(2):135-43.  
Abstract: In previous work, Luthar and Suchman (2000, *Development & Psychopathology*, 12, 235) reported results of a randomized clinical trial testing the efficacy of the Relational Psychotherapy Mothers' Group (RPMG) for methadone-maintained mothers. In this extension, we examined maternal interpersonal maladjustment as a predictor of differential response to RPMG versus standard drug counseling (DC). We predicted that RPMG mothers with high levels of interpersonal maladjustment would improve on parent-child relationship indices, whereas DC mothers with high levels of interpersonal maladjustment would show no improvement. Fifty-two mothers enrolled in the study completed baseline, post-treatment and 6-month followup assessments and a subset of 24 "target" children between the ages of 7 and 16 completed measures on mothers' parenting. As predicted, results of hierarchical regression analyses indicated moderate interpersonal maladjustment x treatment interaction effects for all parenting outcomes at post-treatment and for a subset of outcomes at followup. Plotted interactions confirmed predictions that, as maternal interpersonal maladjustment increased, parenting problems improved for RPMG mothers and remained the same or worsened for DC mothers. Results indicate the potential value of interpersonally oriented interventions for substance-abusing mothers and their children.

Suffczynski P, Lopes da Silva F, Parra J, Velis D, Kalitzin S. Epileptic transitions: model predictions and

experimental validation. *J Clin Neurophysiol* 2005; 22(5):288-99.

Abstract: The essence of epilepsy is that a patient displays (long) periods of normal EEG activity (i.e., nonepileptiform) intermingled occasionally with epileptiform paroxysmal activity. The mechanisms of transition between these two types of activity are not well understood. To provide more insight into the dynamics of the neuronal networks leading to seizure generation, the authors developed a computational model of thalamocortical circuits based on relevant patho(physiologic) data. The model exhibits bistability, i.e., it features two operational states, ictal and interictal, that coexist. The transitions between these two states occur according to a Poisson process. An alternative scenario for transitions can be a random walk of network parameters that ultimately leads to a paroxysmal discharge. Predictions of bistable computational model with experimental results from different types of epilepsy are compared.

Suk WA, Ruchirawat KM, Balakrishnan K *et al.* Environmental threats to children's health in Southeast Asia and the Western Pacific. *Environ Health Perspect* 2003; 111(10):1340-7.

Abstract: The Southeast Asia and Western Pacific regions contain half of the world's children and are among the most rapidly industrializing regions of the globe. Environmental threats to children's health are widespread and are multiplying as nations in the area undergo industrial development and pass through the epidemiologic transition. These environmental hazards range from traditional threats such as bacterial contamination of drinking water and wood smoke in poorly ventilated dwellings to more recently introduced chemical threats such as asbestos construction materials; arsenic in groundwater; methyl isocyanate in Bhopal, India; untreated manufacturing wastes released to landfills; chlorinated hydrocarbon and organophosphorous pesticides; and atmospheric lead emissions from the combustion of leaded gasoline. To address these problems, pediatricians, environmental health scientists, and public health workers throughout Southeast Asia and the Western Pacific have begun to build local and national research and prevention programs in children's environmental health. Successes have been achieved as a result of these efforts: A cost-effective system for producing safe drinking water at the village level has been devised in India; many nations have launched aggressive antismoking campaigns; and Thailand, the Philippines, India, and Pakistan have all begun to reduce their use of lead in gasoline, with resultant declines in children's blood lead levels. The International Conference on Environmental Threats to the Health of Children, held in Bangkok, Thailand, in March 2002, brought together more than 300 representatives from 35 countries and organizations to increase awareness on environmental health hazards affecting children in these regions and throughout the world. The conference, a direct result of

the Environmental Threats to the Health of Children meeting held in Manila in April 2000, provided participants with the latest scientific data on children's vulnerability to environmental hazards and models for future policy and public health discussions on ways to improve children's health. The Bangkok Statement, a pledge resulting from the conference proceedings, is an important first step in creating a global alliance committed to developing active and innovative national and international networks to promote and protect children's environmental health.

Sullivan-Bolyai S, Grey M, Deatrick J, Gruppuso P, Giraitis P, Tamborlane W. Helping other mothers effectively work at raising young children with type 1 diabetes. *Diabetes Educ* 2004; 30(3):476-84. Abstract: PURPOSE: This study examined the feasibility of a postdiagnosis parent mentoring intervention for mothers of young children (1-10 years old) newly diagnosed with type 1 diabetes. METHODS: A mixed-method, prospective, randomized, controlled clinical trial design was used. Parent mentors (experienced mothers who have successfully raised young children with type 1 diabetes) and mother participants with young children newly diagnosed with type 1 diabetes were recruited from 2 regional pediatric diabetes centers. The mentors were trained to provide informational, affirmational, and emotional support using Ireys' modified parent mentor curriculum. During a 6-month trial, mentors provided home visits and phone call support to the mothers who were randomized to the experimental group. The control group had the option of receiving the intervention after the 6-month trial. RESULTS: Mothers in the experimental group had fewer concerns, more confidence, identified more resources, and perceived diabetes having less of a negative impact on their family compared with mothers in the control group. Parent mentors provided important, practical day-to-day management information, reassurance, and emotional support during times of crises. CONCLUSIONS: A postdiagnosis parent mentoring intervention for mothers of children with diabetes appears to be feasible and potentially effective.

Sullivan CO, Omar RZ, Forrest CB, Majeed A. Adjusting for case mix and social class in examining variation in home visits between practices. *Fam Pract* 2004; 21(4):355-63.

Abstract: OBJECTIVES: The purpose of this study was to investigate whether adjusting for clinical case mix and social class explains more of the variation in home

visits between general practices than adjusting for age and sex alone. METHODS: The setting was 60 general practices in England and Wales taking part in the 1 year Fourth National Morbidity Survey. The participants comprised 349 505 patients who were registered with one of the participating general practices for at least 180 days, and who had at least one consultation during the period. The outcome measure is whether or not a patient received a home visit in that year. A clinical case mix category (morbidity class) based on 1 year's diagnostic information was assigned to each patient using the Johns Hopkins Adjusted Clinical Groups (ACG) Case Mix System. The social class measure was derived from occupation and employment status and is similar to that of the 1991 UK census. Variations in home visits between practices were examined using multilevel logistic regression models. The variability between practices before and after adjusting for clinical case mix and social class was estimated using the intracluster correlation coefficient (ICC). RESULTS: The overall percentage of patients receiving a home visit over the 1 year study period was 17%, and this varied from 7 to 31% across the 60 practices. The percentage of the total variation in home visits attributable to differences between practices was 2.5% [95% confidence interval (CI) 1.4-3.2%] after adjusting for age and sex. This reduced to 1.6% (95% CI 1.1-2.4%) after taking into account morbidity class. The results were similar when social class was included instead of morbidity class. Morbidity and social class together reduced variation in home visits between practices to 1.5% (95% CI 1.1-2.2%). CONCLUSIONS: Age, sex, social class and clinical case mix are strong determinants of home visits in the UK. Adjusting for morbidity and social class results in a small improvement in explaining the variability in home visits between practices compared with adjusting for age and sex alone. There is far more variation between patients within practices; however, it is not straightforward to examine the factors influencing this variation. In addition to morbidity and social class, there could also be other unmeasured factors such as varying patient demand for home visits, disability or differences in GP home visiting practice style that could influence the large within-practice variability observed in this study.

Sumanen M, Koskenvuo M, Sillanmaki L, Mattila K. Childhood adversities experienced by working-aged coronary heart disease patients. *J Psychosom Res* 2005; 59(5):331-5.

Abstract: OBJECTIVE: The aim of this study is to investigate associations between childhood adversities and coronary heart disease (CHD). METHODS: This was a case-control study based on a postal questionnaire addressed to randomly selected working-aged Finns, and response rate was 39% (N = 15,477). The sample comprised 319 CHD patients. Four age- and gender-matched controls were selected for every patient. The participants were asked in six questions to

think about their childhood adversities. RESULTS: Fear of some family member and someone in the family being seriously or chronically ill were more common during childhood among working-aged CHD patients than among controls. Likewise, among female CHD patients, serious conflicts in the family and someone in the family having had alcohol problems and, among male CHD patients, long-lasting financial problems were more common than among controls. Odds ratios (OR) varied between 1.27 and 2.66. Adjustment for education had no influence among women, but it had an influence among men. Upon adjustment for conventional risk factors (smoking, obesity, and hypertension), the association mostly disappeared. A family member having been seriously or chronically ill was statistically significant after full adjustment among both genders. CONCLUSION: Working-aged CHD patients have experienced more dramatic events during their childhood than did the control population. This issue cannot be solved in doctors' offices. Health-promoting social policies are of vital importance.

Sundfaer A. [31 women with drug problems got children-- what happened after that?]. *Tidsskr Nor Laegeforen* 2001; 121(1):73-5. Abstract: BACKGROUND: The intention of this study was to increase the knowledge concerning the rehabilitation of women with drug problems after the birth of a child and to find out how the children developed. MATERIAL AND METHODS: A follow-up study of 31 women, former drug and alcohol abusers and their children, 19 girls and 12 boys born in 1982-1983. The first survey took place when the children were 2-3 years of age, then when they were 7-9 and at last when they were 15-17. The biological mothers, foster or adoptive mothers, the children and their teachers were interviewed. RESULTS: The women got more support and control during the pregnancy than afterwards. Most of the mothers became single. Women with the shortest drug history, a good social network and a stable partner without drug problems kept the care of their children. By the first survey (1985), seven children had been placed in foster homes, in the second (1992) two further children had been taken away from their mothers, and in the third (1999) only one third of the children were living with their biological mothers. Most of the children did well at school and in their families, had friends and leisure activities despite still living by their mothers or in foster/adoption homes. None of the youngsters had been in conflict with the law or were drug abusers, but every second teenage girl needed psychological support. Children who had been stable by their drug-free biological mothers functioned best. INTERPRETATION: Mothers with drug problems do not get sufficient attention after the delivery and when the children grow up. A supporting family should be brought in contact with mother and child after the delivery. Under special circumstances pregnancy can

be a positive turning point for women with drug problems.

Sutherland I, Sivarajasingam V, Shepherd JP. Recording of community violence by medical and police services. *Inj Prev* 2002; 8(3):246-7. Abstract: OBJECTIVES: To determine the extent to which community violence that results in injury treated in emergency departments appears in official police records and to identify age/gender groups at particular risk of under-recording by the police. METHODS: Non-confidential data for patients with assault related injury treated in the emergency departments of two hospitals in one South Wales city (Swansea) during a six month period were compared with data relating to all recorded crimes in the category "Violence against the person" in the police area where the hospitals were located. RESULTS: Over the six month period a total of 1513 assaults were recorded by Swansea emergency departments and the police (1019, 67.3% injured males and 494, 32.7% injured females). The majority of these assaults (993, 65.6%) were recorded exclusively by emergency departments; 357 (23.6%) were recorded only by the police and 163 (10.8%) were recorded by both emergency departments and the police. Equal proportions of males (67.3%) and females (67.5%) injured in assaults were recorded by both emergency departments and the police, but men were more likely to have their assault recorded exclusively in emergency departments (odds ratio (OR) 2.1, 95% confidence interval (CI) 1.7 to 2.7) while women were more likely to have their assault recorded exclusively by the police (OR 2.5, 95% CI 2.0 to 3.2). There were no significant relationships between exclusive emergency department recording and increasing age (OR 1.0, 95% CI 0.9 to 1.2), exclusive police recording and increasing age (OR 1.1, 95% CI 1.0 to 1.2), or between age and dual recording (OR 0.9, 95% CI 0.8 to 1.0). CONCLUSIONS: Most assaults leading to emergency department treatment, particularly in which males were injured, were not recorded by the police. Assaults on the youngest group (0-10, particularly boys) were those least likely to be recorded by police and females over age 45, the most likely. Emergency department derived assault data provide unique perspectives of community violence and police detection.

Suzuki K, Morita S, Muraoka H, Niimi Y. [Fetal alcohol spectrum disorders (FASD) among Japanese children of alcoholic mothers]. *Nihon Arukoru Yakubutsu Igakkai Zasshi* 2005; 40(3):219-32. Abstract: OBJECTIVE: This study was carried out to examine fetal alcohol spectrum disorders (FASD) among Japanese children of alcoholic mothers. This is the first report concerning FASD in Japan. METHODS: The subjects were 30 alcoholic women who were inpatients in the Kurihama Alcoholism Center and had given birth to children. They were subjected to a semi-structured interview by the author. Sixty healthy women who had not drunk during

pregnancy were used as a control group, and they also underwent semi-structured interviews. The alcoholic women were divided into two groups, 13 who drank during pregnancies and 17 who did not drink. Twenty children experienced of prenatal alcohol exposure and 40 children did not. The three groups; i.e., 13 alcoholic mothers who had drunk during pregnancy and their 20 children (ALD group), 17 alcoholic mothers who had not drunk during pregnancy and their 40 children (ALND group) and 60 non-alcoholic control mothers and their 80 children (Control group), were compared concerning the mothers' drinking problems and abnormal deliveries, children's birth weights, congenital abnormalities, abnormalities of the central nervous system and psychological problems. RESULTS: The mean age of onset of problem drinking of the mothers in the ALD group was significantly lower than that in the mothers of the ALND group, and some of the mothers in the ALD group showed alcohol dependence before their pregnancies. The mean birth weights of the children of the ALD group, ALND group and Control group were 2816 g, 3128 g and 3142 g, respectively and the differences were significant. The children of the ALD group had significantly more abnormal birth episodes, developmental retardation and psychiatric symptoms than those in the other two groups. Among 20 children in the ALD group, FASD was suspected in 6 children (10% of the children of alcoholic mothers). Six children had low birth weights, abnormal birth episodes, mental retardation and psychiatric symptoms. CONCLUSION: One third of the Japanese children of alcoholic mothers had experiences of prenatal alcohol exposure and 10% of them had suspected FASD abnormalities.

Swahn MH, Mahendra RR, Paulozzi LJ *et al.* Violent attacks on Middle Easterners in the United States during the month following the September 11, 2001 terrorist attacks. *Inj Prev* 2003; 9(2):187-9. Abstract: OBJECTIVES: To document and describe hate related violent attacks on Middle Easterners or those perceived to be Middle Easterners during the month following the September 11, 2001 terrorist attacks in New York City and Washington, DC. METHODS: The LexisNexis database of newspaper reports were used to identify incidents of hate related violent acts against Middle Easterners or those perceived to be Middle Easterners in the US between September 1 and October 11, 2001. A total of 100 incidents of hate related violence were identified in the 2659 news articles that were reviewed. RESULTS: Of the 100 incidents of violent victimization that took place during the period September 1 to October 11, only one incident occurred before September 11. The

99 incidents that occurred after September 11 involved at least 128 victims and 171 perpetrators. Most violent victimizations occurred within 10 days of the attacks, involved male perpetrators and male victims, and occurred in convenience stores, on the streets, at gas stations, at schools/colleges, and at places of worship. DISCUSSION: Most violent victimizations occurred in the 10 days immediately following the terrorist attacks indicating that interventions that promote tolerance and understanding of diversity need to be implemented quickly in order to be effective. In addition, patrolling by police and Neighborhood Watch programs around convenience stores and gas stations may also be effective strategies for reducing hate related violent crimes.

Swanson EF. Anchors of the community: community schools in Chicago. *New Dir Youth Dev* 2005; (107):55-64, table of contents. Abstract: In partnership with Chicago's public and private sectors, Chicago Public Schools (CPS) has successfully implemented a citywide education reform effort, designed to transform Chicago's neighborhood schools into vibrant centers of the community. Mayor Richard M. Daley and Arne Duncan, CEO of CPS, launched the Community Schools Initiative in January 2002. What started as an idea that was developed by a local foundation has now grown into the largest-scale community school effort in the nation, with sixty-seven schools in operation and a plan to move to one hundred community schools by 2007. This initiative currently involves seventeen private funders, ten technical assistance providers, thirty-four community-based organizations that offer on-site services to children and families, and over three hundred additional community partnerships that provide one-day events such as health fairs and violence prevention workshops.

Swanson T. Mighty like a rose. *Pediatr Rehabil* 2004; 7(3):221-3.

Sweatt L, Harding CG, Knight-Lynn L, Rasheed S, Carter P. Talking about the silent fear: adolescents' experiences of violence in an urban high-rise community. *Adolescence* 2002; 37(145):109-20. Abstract: The self-reported violent experiences of adolescents living in a public-subsidized urban high-rise building were examined. This effort was part of an interdisciplinary, community-university collaboration program called the HOME (High-rise On-site Multifamily Environments) Family Support Project. A survey of violent experiences and a one-on-one structured interview were conducted with 20 adolescent residents. Results of the quantitative and qualitative analyses revealed high degrees of exposure to violence among these adolescents, concerns for their personal safety, as well as insights into what they believe adults could and should be doing to address increasing levels of community violence. The

implications of these results for conducting ecologically valid research on sensitive issues with adolescents and for family support program planning are discussed.

Swick SD, Jellinek MS, Dechant E, Jellinek MS, Belluck J. Children of victims of September 11th: a perspective on the emotional and developmental challenges they face and how to help meet them. *J Dev Behav Pediatr* 2002; 23(5):378-84.

Sword W, Niccols A, Fan A. "New Choices" for women with addictions: perceptions of program participants. *BMC Public Health* 2004; 4:10. Abstract: BACKGROUND: Substance use in pregnancy is a major public health problem. It can have profound effects on pregnancy outcomes, and childhood health and development. Additionally, women who use substances have their own health-related issues. Although intervention is important, these women often have difficulty using traditional systems of care. The New Choices program is a centralized, multi-sector approach to service delivery that has attempted to overcome barriers to care by offering one-stop shopping in a supportive environment. As part of an evaluation of this program designed for women who are pregnant and/or parenting young children, interviews were conducted with participants to gain insight into their experiences in New Choices and perceptions of any changes attributed to program involvement. METHODS: A qualitative, exploratory design was used to guide data collection and analysis. Four women participated in a focus group interview and seven women agreed to individual interviews over the course of the program evaluation (N = 11). A semi-structured interview guide was used to explore women's experiences in New Choices and their perceptions of the program and its impact. The interview data were analyzed using NVivo software and an inductive approach to data analysis. RESULTS: The emergent themes captured women's motivations for attending New Choices, benefits of participation, and overall quality of the program. Children were the primary motivating factor for program enrollment. Perceived benefits included decreased substance use, improved maternal health, enhanced opportunity for employment, increased access to other resources, enhanced parenting skills, and improved child behaviour and development. Women highly valued the comprehensive and centralized approach to service delivery that provided a range of informal and formal supports. CONCLUSIONS: Interview findings endorse the appropriateness and potential efficacy of a collaborative, centralized approach to service provision for women with substance use issues. Although the findings provide insight into an alternative model of service delivery for women with addictions, future research is needed to evaluate the effectiveness of the intervention. Research also is needed to determine which program components or constellation of

components contribute to desired outcomes, and to learn more about processes that underlie changes in behaviour.

Sylvestre A, Payette H, Tribble DS. [The prevalence of communication problems in neglected children under three years of age.]. *Can J Public Health* 2002; 93(5):349-52.

Abstract: OBJECTIVE: Estimate the prevalence of communication problems in children under three taken into care by Youth Centres in Quebec for negligence. Prevalence is calculated for the pragmatic aspect, receptive and expressive language, according to age and sex. METHOD: This is a cross-sectional study. A representative sample of 84 children was drawn consecutively from the lists of new children registered at the Youth Centres. RESULTS: 46.4% of the children present a problem in at least one area of communication. The prevalence and seriousness of the problems increase significantly with age. Boys are significantly more affected than girls. CONCLUSION: Negligence constitutes a threat to the development of communication. According to the data reported in this study, there is substantial justification for early intervention, promotion and prevention programs with regard to communication problems among neglected children.

Szilagyi PG, Schaffer S, Shone L *et al.* Reducing geographic, racial, and ethnic disparities in childhood immunization rates by using reminder/recall interventions in urban primary care practices. *Pediatrics* 2002; 110(5):e58.

Abstract: CONTEXT: An overarching national health goal of Healthy People 2010 is to eliminate disparities in leading health care indicators including immunizations. Disparities in US childhood immunization rates persist, with inner-city, black, and Hispanic children having lower rates. Although practice or clinic-based interventions, such as patient reminder/recall systems, have been found to improve immunization rates in specific settings, there is little evidence that those site-based interventions can reduce disparities in immunization rates at the community level. OBJECTIVE: To assess the effect of a community-wide reminder, recall, and outreach (RRO) system for childhood immunizations on known disparities in immunization rates between inner-city versus suburban populations and among white, black, and Hispanic children within an entire county. SETTING: Monroe County, New York (birth cohort: 10 000, total population: 750 000), which includes the city of Rochester. Three geographic regions within the county were compared: the inner city of Rochester, which contains the greatest concentration of poverty (among 2-year-old children, 64% have Medicaid); the rest of the city of Rochester (38% have Medicaid); and the suburbs of the county (8% have Medicaid). INTERVENTIONS: An RRO system was implemented in 8 city practices in 1995 (covering 64% of inner-city

children) and was expanded to 10 city practices by 1999 (covering 74% of inner-city children, 61% of rest-of-city children, and 9% of suburban children). The RRO intervention involved lay community-based outreach workers who were assigned to city practices to track immunization rates of all 0- to 2-year-olds, and to provide a staged intervention with increasing intensity depending on the degree to which children were behind in immunizations (tracking for all children, mail, or telephone reminders for most children, assistance with transportation or scheduling for some children, and home visits for 5% of children who were most behind in immunizations and who faced complex barriers). **STUDY PARTICIPANTS:** Three separate cohorts of 0- to 2-year-old children were assessed—those residing in the county in 1993, 1996, and 1999. **STUDY DESIGN:** Immunization rates were measured for each geographic region in Monroe County at 3 time periods: before the implementation of a systematic RRO system (1993), during early phases of implementation of the RRO system (1996), and after implementation of the RRO system in 10 city practices (1999). Immunization rates were compared for children living in the 3 geographic regions, and for white, black, and Hispanic children. Immunization rates were measured by the same methodology in each of the 3 time periods. A denominator of children was obtained by merging patient lists from the practice files of most pediatric and family medicine practices in the county (covering 85% to 89% of county children). A random sample of children (>500 from the suburbs and >1200 from the city for each sampling period) was then selected for medical chart review at practices to determine demographic characteristics (including race and ethnicity) and immunization rates. City children were oversampled to allow detection of effects by geographic region and race. Rates for the 3 geographic regions and for the entire county were determined using Stata to adjust for the clustered sampling. **MAIN OUTCOME MEASURES:** Immunization rates at 12 and 24 months for recommended vaccines (4 diphtheria-tetanus-pertussis:3 polio:1 measles-mumps-rubella: > or =1 Haemophilus influenzae type b on or after 12 months of age). **RESULTS: DISPARITIES BY GEOGRAPHIC REGION:** Baseline immunization rates (1993) for 24-month-olds were as follows: inner city (55%), rest of city (64%), and suburbs (73%), with an 18% difference in rates between the inner city and suburbs. By 1996, immunization rates rose faster in the inner city (+21% points) than in the suburbs (+14% points) so that the difference in rates between the inner city and suburbs had narrowed to 11%. In 1999, rates were similar across geographic regions: inner city (84%), rest of city (81%), and suburbs (88%), with a 4% difference between the inner city and suburbs. **DISPARITIES BY RACE AND ETHNICITY:** Immunization rates were available in 1996 and 1999 by race and ethnicity. Twenty-four-month immunization rates in 1996 showed disparities: white (89%), black (76%), and Hispanic (74%), with a 13% difference

between rates for white and black children and a 15% difference between white and Hispanic children. In 1999, rates were similar across the groups: white (88%), black (81%), and Hispanic (87%), with a 7% difference between rates for white and black children, and a 1% difference between white and Hispanic children. **CONCLUSIONS:** A community-wide intervention of patient RRO raised childhood immunization rates in the inner city of Rochester and was associated with marked reductions in disparities in immunization rates between inner-city and suburban children and among racial and ethnic minority populations. By targeting a relatively manageable number of primary care practices that serve city children and using an effective strategy to increase immunization rates in each practice, it is possible to eliminate disparities in immunizations for vulnerable children.

Sznajder M, Leduc S, Janvrin MP *et al.* Home delivery of an injury prevention kit for children in four French cities: a controlled randomized trial. *Inj Prev* 2003; 9(3):261-5; discussion 265.  
**Abstract: OBJECTIVES:** Home delivery of counselling and safety devices to prevent child injuries could help parents to adopt safe behaviour. The aim of this study was to test a safety kit designed and used in Quebec (Canada). **DESIGN AND SUBJECTS:** One hundred families from four towns in the Paris suburbs were visited at home by nurses or doctors when their child reached 6-9 months. Selection criteria were: primipara, medical problem, psychological, and/or socioeconomic difficulties. **INTERVENTIONS:** During the first visit, 50 families (group 1) received counselling and a kit including preventive devices and pamphlets about indoor injuries and ways to avoid them. The other 50 families (group 2) received counselling but not the kit. A second home visit was made 6-8 weeks later. **MAIN OUTCOME MEASURES:** The number of safety improvements was calculated 6-8 weeks after a first home visit. Perceived usefulness of the kit was collected from families and from interviewers. **RESULTS:** Between the first and the second visits, safety improvement was significantly higher in the group with the kit. This was mainly related to the risk of fall ( $p < 0.02$ ), fire and burns ( $p < 0.001$ ), poisoning ( $p < 0.01$ ), and suffocation ( $p < 0.001$ ). For improvement related to devices provided in the kit, the difference between the groups was significant: 64.4% improvement in group 1 versus 41.2% in group 2 ( $p < 0.01$ ). The relative risk (RR) of safety improvement between groups was 1.56 (95% confidence interval (CI) 1.35 to 1.80). Even for improvements not related to the kit the difference remained significant: 31.2% in group 1 versus 20.2% in group 2 ( $p < 0.05$ ); RR = 1.54 (95% CI 1.22 to 1.93). **CONCLUSION:** Routine home visits by social services offer a good opportunity to tackle child injury prevention. Free delivery of prevention kits and counselling allow families to modify their behaviour and homes so as to reduce

risks.

Szpurek D, Moszynski R, Smolen A, Sajdak S. Artificial neural network computer prediction of ovarian malignancy in women with adnexal masses. *Int J Gynaecol Obstet* 2005; 89(2):108-13. Abstract: OBJECTIVE: Assessment of the usefulness of a neural model to predict which ovarian tumors are malignant. METHOD: Age, menopausal status, body mass index, grayscale and Doppler ultrasonographic features, as well as levels of specific markers (CA 125, tissue polypeptide specific antigen) were examined in 686 women with adnexal masses. The probability of malignancy was calculated using an artificial neural network software and the diagnostic efficiency of the received model was estimated using a receiver-operating characteristics (ROC) curve. RESULT: Of the 686 women, 431 (62.8%) had a benign and 255 (37.2%) had a malignant ovarian tumor. The significant malignancy predictors are age, menopausal status, maximum tumor diameter, internal wall structure of tumor, presence of septa and/or solid elements, tumor location, location of vessels, and blood flow indexes. The best network provided 96.0% sensitivity and 97.7% specificity. The area under the curve for the received model was 0.9716. CONCLUSIONS: An artificial neural network model based on clinical and ultrasonographic data allows to calculate the probability of tumor malignancy.

Szwarcwald CL, Bastos FI, Andrade CL. [Health inequality indicators: a discussion of some methodological approaches as applied to neonatal mortality in the Municipality of Rio de Janeiro, 2000]. *Cad Saude Publica* 2002; 18(4):959-70. Abstract: Epidemiology has investigated the relationship between health status and different social and economic factors ever since the field emerged. Studies have consistently shown that the population's health status bears a strong social gradient, invariably unfavorable to the less privileged groups. Increasing interest in understanding and characterizing health inequalities has broadened the discussion in the recent literature on appropriate concepts and methodological procedures for measuring differences in health status according to socioeconomic level. This study presents a critical assessment of health inequality indicators, focusing on the following: the redistribution principle and its application to health status; the influence of income inequality; epidemiological and statistical approaches to the problem; and evaluation of health system performance in reducing health inequalities. As an example, inequalities in the neonatal mortality rate are analyzed in the city of Rio de Janeiro, Brazil, 2000, according to the mother's level of schooling, reviewing the minimum requisites for defining an adequate health inequality indicator.

Subfactors of DSM-IV conduct disorder: evidence and connections with syndromes from the Child Behavior Checklist. *J Abnorm Child Psychol* 2003; 31(6):647-54.

Abstract: Is conduct disorder (CD) as defined in the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV; American Psychiatric Association, 1994) a unitary entity, or do variants of CD exist? We addressed this question, using data collected from the parents of 1,669 Australian boys, aged 6-17. Parents were interviewed to assess DSM-IV Conduct Disorder (DSM-IV CD) criteria. Results revealed 2 subfactors of DSM-IV CD symptoms, made up of overt behaviors (e.g., initiating physical fights) and covert behaviors (e.g., stealing without confrontation). Ordinary least squares regressions showed the 2 CD subfactors to be significantly and uniquely predicted by Child Behavior Checklist (CBCL; T. M. Achenbach, 1991a, 1991b) syndromes labeled Aggressive Behavior and Delinquent Behavior, respectively. The results are discussed in terms of the utility of differentiating these 2 variants of CD in future editions of the DSM.

Taft A, Broom DH, Legge D. General practitioner management of intimate partner abuse and the whole family: qualitative study. *BMJ* 2004; 328(7440):618. Abstract: OBJECTIVE: To explore management by general practitioners of victimised female patients, male partners who abuse, and children in the family. DESIGN: Triangulated qualitative study comparing doctors' reported management with current recommendations in the literature. PARTICIPANTS: 28 general practitioners attending continuing medical education about management of domestic violence. RESULTS: Doctors perceived partner abuse in diverse ways. Their gender, perceptions, and attitudes could all affect identification and management of this difficult problem. A few doctors practised in recommended ways, but many showed stress and aversion, difficulties in resolving the tensions involved in managing all family members, and neglect of the risks to children. Some doctors used contraindicated practices, such as breaking confidentiality and undertaking or referring for couple counselling. Doctors who were not familiar with community based agencies were reluctant to use them. A lack of expertise and support could have a negative impact on doctors themselves. CONCLUSIONS: General practitioners managing partner abuse need to be more familiar with and apply the central principles of confidentiality and safety of women and children. Recommended guidelines for managing the whole family should be developed. Doctors should consider referring one partner elsewhere and avoid couple counselling; always ask about and act on the children's welfare; refer to specialist family violence agencies; and seek training, supervision, and support for the inherent stress. Medical education and administration should ensure comprehensive training and support for doctors undertaking this difficult work.

Tagge ME. Wet nursing 2001: old practice, new dilemmas? *J Hum Lact* 2001; 17(2):140-1.

Tagle R. Full-service community schools: cause and outcome of public engagement. *New Dir Youth Dev* 2005; (107):45-54, table of contents. Abstract: Public Education Network (PEN)-a national organization of local education funds (LEFs)-along with individuals working to improve public schools and build citizen support for quality public education, embarked on an initiative to address the academic, enrichment, and social support needs of young people to ensure their success in and out of school. PEN's Schools and Community Initiative called for the active participation of broad constituencies-policymakers, stakeholders, and the public-at-large-to create and implement their common vision for full-service community schools. By engaging broad constituencies across communities, LEFs have been able to build strong relationships between and among community institutions under a common vision.

Taguchi T, Suita S, Masumoto K, Nada O. Universal distribution of c-kit-positive cells in different types of Hirschsprung's disease. *Pediatr Surg Int* 2003; 19(4):273-9.

Abstract: Interstitial cells of Cajal (ICCs) have been reported to play the role of a pacemaker in regulating bowel motility. The relationship between neurons and ICCs, however, remains unclear. Hirschsprung's disease (HD) is an ideal model for investigating this relationship. The operated specimens obtained from 6 short and 3 long segment aganglionosis patients and 3 controls were used as the subject materials in this study. ICCs were immunohistochemically identified using a specific antiserum c-kit, a tyrosine kinase receptor expressing ICCs. Nitroergic nerves were demonstrated by NADPH-diaphorase (NADPH-d) histochemistry. C-kit immunohistochemistry was also combined with protein gene product 9.5 (PGP 9.5; as a general neuronal marker). In the normoganglionic segment of HD, numerous c-kit-positive cells and NADPH-d positive neurons were found in the proper muscle layer, including Auerbach's plexus. In the oligoganglionic segment, the number of c-kit-positive cells and NADPH-d neurons slightly decreased. In the inner border of the circular muscle layer (IBCM), the c-kit-positive cell networks and NADPH-d activities remained in short segment cases, while both of them were absent in the long segment cases. In the aganglionic segment, c-kit positive cells were present universally but the number of them was slightly decreased in the proper muscle layer. The c-kit-positive cell networks of IBCM were seen where extrinsic neurons were present, while they were almost completely absent where extrinsic neurons were absent in the proximal zone of the long segment cases. C-kit positive cells were present universally in the oligoganglionic as well as aganglionic segments of HD. The distribution and properties of c-kit positive

cells were related to the presence of extrinsic neurons in aganglionic segment. Based on these findings, aperistalsis is considered not to relate with c-kit positive cells, and c-kit positive cells are not supposed to have a neurogenic origin and can develop without neurons, however the lack of enteric neurons may influence the full differentiation of ICCs.

Takeshita K, Nagamine T, Thuy DH *et al.* Maturational change of parallel auditory processing in school-aged children revealed by simultaneous recording of magnetic and electric cortical responses. *Clin Neurophysiol* 2002; 113(9):1470-84. Abstract: OBJECTIVES: To elucidate the maturational change of cortical auditory processing, we analyzed simultaneously recorded auditory evoked potentials (AEPs) and magnetic fields (AEFs) in school-aged children. METHODS: Simultaneous recording of AEP and AEF were performed in 32 healthy children of age ranging from 6 to 14 years and 10 adults. Tone bursts of 1 kHz were presented to the left and right ears alternately with 3 different within-ear stimulus onset asynchronies (SOAs) (1.6, 3.0 and 5.0 s for each ear) under attention-distracted condition. RESULTS: All subjects showed clear N100 and N100m peaks under the longest SOA condition (5.0 s). Under the shortest SOA condition (1.6 s), 4 out of 19 subjects under 12 years (21%) failed to show the N100m component. By contrast, N250 and N250m were observed in the majority of children (29/32: 91%) while those were detected in only 4 out of 10 adults (40%). The spatial distribution of N100 in children under 9 years differed from that in older subjects, whereas the dipole orientation of N100m was constant among age groups, suggesting that radially oriented sources might make additional contribution to the generation of N100 in early childhood. N250 was significantly larger in children than in adults. The strength of N250 was suppressed with longer SOAs, whereas that of N100 was enhanced. The dipole of N250m was located around Heschl's gyrus on the superior temporal plane which was significantly medial, anterior and inferior to that of N100m. CONCLUSIONS: Dissociation of maturational change between the tangential and radial components of N100 suggests that auditory processing at around 100 ms consists of multiple parallel pathways which mature independently. Furthermore, a negative peak at around 250 ms specifically seen in children has different generators from N100 and might represent a special auditory processing which takes an active part until acquisition of the efficient cortical networks of the adult brain.

Taket A, Nurse J, Smith K *et al.* Routinely asking women

about domestic violence in health settings. *BMJ* 2003; 327(7416):673-6.

Takeuchi H, Inoue M, Watanabe N *et al.* Parental enforcement of bedtime during childhood modulates preference of Japanese junior high school students for eveningness chronotype. *Chronobiol Int* 2001; 18(5):823-9.

Abstract: We examined the effect of home bedtime discipline during childhood on morningness and eveningness (M-E) preference by Japanese junior high school students. M-E was assessed by the M-E Questionnaire (MEQ) of Torsvall and Akerstedt (the higher the score, the greater the preference for morningness), and parental determination of bedtime during childhood was ascertained using an original questionnaire. The average M-E score of adolescents living in urban Kochi City (mean  $\pm$  SD; 15.10  $\pm$  3.42) was significantly lower ( $P < .01$ ) than the score of those in suburban districts (16.14  $\pm$  3.44). Overall, 43.1% of the junior high school students in Kochi City compared to 53.0% of the students living in suburban districts had their bedtime decided during childhood by parents ( $P < .01$ ). In Kochi City, the M-E score for boys (14.62  $\pm$  3.51) was lower ( $P < .01$ ) than girls (15.53  $\pm$  3.28). During childhood, parents decided the bedtime for 49% of the girls compared to 36.6% of the boys ( $P < .01$ ). Boys whose bedtime was not decided by parents during childhood had a somewhat stronger preference for eveningness (14.20  $\pm$  3.53) ( $P < .05$ ) compared to those whose bedtime was decided by parents (15.12  $\pm$  3.36). The results suggest bedtime discipline at home during childhood has an effect on adolescent chronotype, modulating the extent of shift to eveningness in Japanese junior high school boys in particular.

Talbert DG. Paroxysmal cough injury, vascular rupture and 'shaken baby syndrome'. *Med Hypotheses* 2005; 64(1):8-13.

Abstract: It is widely assumed that subdural and retinal haemorrhage in infants can only result from traumatic rupture of vulnerable blood vessels. An alternative aetiology, that of vascular rupture resulting from excessive intraluminal pressure, is presented in three disease conditions. (1) Perlman *et al.*, studying premature neonates requiring mechanical ventilation for respiratory distress syndrome, observed "cough-like" fluctuations in oesophageal pressure greater than 18 cms H<sub>2</sub>O, whose timing matched fluctuations in anterior cerebral artery flow. When 14 out of 24 neonates were paralysed (to prevent abdominal muscle activity) intraventricular haemorrhage developed in all 10 controls but in only one of the paralysed group during paralysis. (2) New analysis of pressure data extracted from a previous study of prolonged expiratory apnoea showed alveolar collapse induced 100 mmHg intrathoracic cough pressure surges. Superior vena cava pressures up to 50 mmHg were implied, and radial artery systolic pressures over 180

mmHg recorded. (3) *Bordetella pertussis* bacteria attach to cilia in the airways, but do not invade the underlying tissue. The irritation causes the powerful coughing paroxysms of whooping cough. Brain haemorrhages and retinal detachment have been observed to result from the high intravascular pressures produced. The data suggest that any source of intense airway irritation not easily removed (laryngeal infection, inhalation of regurgitated feed, fluff, smoke etc.) could induce similar bleeding, a paroxysmal cough injury (PCI). Additional objective evidence of inflicted trauma is necessary to distinguish between 'shaken baby syndrome' and PCI.

Tam CM, Leung CC, Noertjojo K, Chan SL, Chan-Yeung M. Tuberculosis in Hong Kong-patient characteristics and treatment outcome. *Hong Kong Med J* 2003; 9(2):83-90.

Abstract: OBJECTIVES: To identify the general characteristics of patients with tuberculosis, and to evaluate their treatment outcomes. DESIGN: Retrospective study. SETTING: Tuberculosis and Chest Service, Department of Health, Hong Kong. SUBJECTS AND METHODS: All patients with tuberculosis registered for treatment from 1 January 1996 to 31 December 1996 were included in the study. Information was extracted from their medical records at treatment commencement and at 12 and 24 months after treatment was instigated. Data gathered included demographic data, past treatment, site of disease, case category, treatment regimen, bacteriological status, and treatment outcome. RESULTS: There were 5757 patients for analysis. Approximately one third of patients were aged 60 years or older, and 69.1% were male. Pulmonary disease alone occurred in 77.7% of patients, while both pulmonary and extrapulmonary diseases occurred in 8.6%. New patients comprised 84.6% of cases, and 16.3% had concomitant illnesses. There was excess risk of disease among patients who were male, elderly, or who had silicosis. Only 0.1% of patients were co-infected with human immunodeficiency virus infection. Among the 5757 cases evaluated, 1324 (23.0%) were new patients with a positive sputum smear, 299 (5.2%) were patients who were retreated with a positive sputum smear, and 4134 (71.8%) were new or retreatment patients with a negative sputum smear. The overall treatment completion rates at 12 and 24 months were 80.4% and 84.8%, respectively. Males and patients aged 60 years or older had lower treatment completion rates. Non-adherence, transfer to other services, and mortality among the elderly were key factors influencing treatment outcomes. Co-morbidity was associated with better case-holding, and this more than compensated for its effect on prolongation of treatment and mortality. CONCLUSIONS: There was an excess risk of tuberculosis among male and elderly patients, who also had a less favourable outcome. Active screening of clearly identified risk groups may be appropriate but requires the completion of more in-depth studies and

careful cost-effectiveness analyses. Further efforts with respect to case-holding are indicated to address treatment defaulting and transfer rates.

Tamburlini G, Ronfani L, Buzzetti R. Development of a child health indicator system in Italy. *Eur J Public Health* 2001; 11(1):11-7.

Abstract: **BACKGROUND:** The need for a uniform, comprehensive and action-oriented child health indicator system is widely recognised. As part of a Ministry of Health project, a working group was established in Italy in order to develop a proposal for a minimum set of health indicators to be adopted at the regional and local health authority levels, where the planning process takes place. **METHODS:** The indicators proposed cover 17 areas of perinatal, child and adolescent health. The informing principles for the choice were relevance to the main health problems, availability of a reliable data collection system, feasibility of the collection and analysis process at the two health system levels proposed and extent to which the information provides clues for policy options. **RESULTS:** The main difficulties arise from a lack of uniform systems of classification and data collection for disabilities, as well as adequate tools for assessing quality of care and quality of life. A basic framework for analysis is suggested, including further breakdown of the indicators proposed, such as analysis by birthweight and by cause of neonatal death and by mother's education and father's employment. The information provided by the health indicators put forward needs to be evaluated within the broader scenario of the child's situation so that associated factors may be identified and clues found for intersectoral policies. Two research projects were started to evaluate the feasibility and reliability of data collection and the impact on the planning process at both the regional and local health authority levels. **CONCLUSION:** A European-wide initiative is proposed to tackle existing methodological problems effectively and develop a common child health indicator system.

The relation between the absolute level of parenting and differential parental treatment with adolescent siblings' adjustment. *J Child Psychol Psychiatry* 2004; 45(8):1397-406.

Abstract: **BACKGROUND:** The present study extends existing studies on the role of differential parental treatment in explaining individual differences in adolescent problem behaviors above the absolute level of parenting and clarifies the function of gender of the child, birth rank and gender constellation of the sibling dyads. **METHOD:** The absolute level of parenting practices and differential treatment were examined in a sample of 288 Dutch families consisting of two parents and two adolescents. Parents reported on adolescent internalizing and externalizing problem behavior and adolescents reported on parental warmth and coercive

control. **RESULTS:** Parenting dimensions were related to problem behavior for same- and mixed-gender sibling pairs, with coercive control as the strongest predictor. No direct association was found between differential parental treatment and child outcomes above the absolute levels of parenting in same-gender sibling pairs. However, differential maternal and paternal control was related to internalizing behavior of girls and differential paternal warmth was linked to externalizing behavior of the older siblings in mixed-gender sibling pairs. **CONCLUSION:** Differential parental treatment is uniquely associated with child problem behavior above the absolute level of parenting for girls and early-born children in mixed-gender sibling pairs. Any examination of the effects of differential treatment should not be undertaken without considering the gender and birth rank of the sibling pairs.

Tan KC, Yu Q, Heng CM, Lee TH. Evolutionary computing for knowledge discovery in medical diagnosis. *Artif Intell Med* 2003; 27(2):129-54.

Abstract: One of the major challenges in medical domain is the extraction of comprehensible knowledge from medical diagnosis data. In this paper, a two-phase hybrid evolutionary classification technique is proposed to extract classification rules that can be used in clinical practice for better understanding and prevention of unwanted medical events. In the first phase, a hybrid evolutionary algorithm (EA) is utilized to confine the search space by evolving a pool of good candidate rules, e.g. genetic programming (GP) is applied to evolve nominal attributes for free structured rules and genetic algorithm (GA) is used to optimize the numeric attributes for concise classification rules without the need of discretization. These candidate rules are then used in the second phase to optimize the order and number of rules in the evolution for forming accurate and comprehensible rule sets. The proposed evolutionary classifier (EvoC) is validated upon hepatitis and breast cancer datasets obtained from the UCI machine-learning repository. Simulation results show that the evolutionary classifier produces comprehensible rules and good classification accuracy for the medical datasets. Results obtained from t-tests further justify its robustness and invariance to random partition of datasets.

Impact of school nurse case management on students with asthma. *J Sch Health* 2004; 74(6):213-9. Abstract: This project determined asthma prevalence in a large school district, absentee rates, and potential effects of school nurse case management for student asthma over three years. Data were derived from an asthma tracking tool used by nurses in one school district for every student reported as having asthma by their parent. School nurses began collecting data in their schools in 1999-2000 when an asthma-management protocol was first developed. Nurses

documented perceived asthma severity for each student, presence of medication and peak flow meters in school, and case management activities provided. This data base was cross matched with percentage of days students were absent for any illness. Prevalence of asthma, based on school nurse records of parent report, was between 5.1% to 6.2% during the three years. Between 13.5% and 15% were moderate or severe. Students with asthma were absent between one-half to one and one-quarter days more often than those without asthma. In year three, 39% of students with asthma had medication at school, and 12% had a peak flow meter. Contacting a parent was the nurse case management activity provided for the largest number of students (27% of students with asthma), followed by asthma education (16.5%), contact with physician (6%), and home visits (1%). Students who received at least one school nurse case management intervention were more likely the next year to have an asthma medication at school, to use a peak flow meter at school, and to have a change in asthma severity. School nurse case management activity had no association with student absences. Availability of medication and peak flow meters at school was low, suggesting standards of care for asthma were not followed. School nurse case management, when performed outside a project or intervention, offers a promising strategy to improve asthma management.

Tarter RE. Etiology of adolescent substance abuse: a developmental perspective. *Am J Addict* 2002; 11(3):171-91.

Abstract: Approximately 5% of adolescents in the U.S. qualify for a diagnosis of substance use disorder (SUD). Low affect and behavior self-regulation during child development interacting with family, peer and other ecological factors predisposes to substance use in adolescence. Maturation processes during adolescence, particularly involving the brain and reproductive system, exacerbate the low psychological self-regulation evidenced during childhood to promote initiation of alcohol, tobacco, and other drug (ATOD) consumption. This discussion examines the etiology of ATOD abuse and SUD from a developmental perspective. The ramifications of a developmental perspective for clinical practice and social policy are also considered.

Tarter RE, Kirisci L, Mezzich A *et al.* Neurobehavioral disinhibition in childhood predicts early age at onset of substance use disorder. *Am J Psychiatry* 2003; 160(6):1078-85.

Abstract: OBJECTIVE: This longitudinal study had three aims: 1) determine the extent to which boys at high average risk and low average risk for substance use disorder differ on a construct of neurobehavioral disinhibition, 2) evaluate the capacity of neurobehavioral disinhibition to predict substance use frequency at age 16, and 3) demonstrate the utility of neurobehavioral disinhibition in predicting substance use disorder. METHOD: The authors derived an index of neurobehavioral disinhibition from measures of affect, behavior, and cognition. The neurobehavioral disinhibition score was used to discriminate youth at high and low average risk for substance use disorder and to predict substance use frequency after 4-6 years and substance use disorder after 7-9 years. RESULTS: The neurobehavioral disorder score significantly discriminated boys at high average risk from those at low average risk at ages 10-12. Neurobehavioral disinhibition at age 16, in conjunction with substance use frequency and risk status group, predicted substance use disorder at age 19 with 85% accuracy and accounted for 50% of the variance in Drug Use Screening Inventory overall problem density score. Neurobehavioral disinhibition was a stronger predictor of substance use disorder (odds ratio=6.83) than substance consumption frequency (odds ratio=3.19). CONCLUSIONS: Cross-sectional and longitudinal analyses indicated that neurobehavioral disinhibition is a component of the liability to early age at onset of substance use disorder.

Tarter RE, Kirisci L, Reynolds M, Mezzich A. Neurobehavior disinhibition in childhood predicts suicide potential and substance use disorder by young adulthood. *Drug Alcohol Depend* 2004; 76 Suppl:S45-52.

Abstract: The objectives of this study were to (a) determine whether two factors that are established components of the risk for substance use disorder (SUD) also impact on the risk for suicide; and (2) evaluate whether SUD manifest by early adulthood predicts suicide propensity. Neurobehavior disinhibition assessed in 227 boys at ages 10-12 and 16 and parental history of SUD were prospectively evaluated to determine their association with the risk for SUD and suicide propensity between ages 16 and 19. The results indicated that neurobehavior disinhibition at age 16 predicts suicide propensity between ages 16 and 19 ( $p = .04$ ). A trend was observed ( $p = .08$ ) for SUD manifest between ages 16 and 19 to predict suicide propensity during the same period. Maternal SUD is directly associated with son's SUD risk but not suicide propensity. Paternal SUD predicts son's neurobehavior disinhibition that, in turn, predisposes to SUD. A direct relation between paternal SUD and son's suicide propensity was not observed. These findings suggest that neurobehavior disinhibition, a component of the liability of SUD, is also associated with suicide risk. These results are discussed within a neurobehavioral framework in

- which prefrontal cortex dysfunction is hypothesized to underlie the risk for these two outcomes.
- Taveras EM, Capra AM, Braveman PA, Jensvold NG, Escobar GJ, Lieu TA. Clinician support and psychosocial risk factors associated with breastfeeding discontinuation. *Pediatrics* 2003; 112(1 Pt 1):108-15. Abstract: OBJECTIVE: Breastfeeding rates fall short of goals set in Healthy People 2010 and other national recommendations. The current, national breastfeeding continuation rate of 29% at 6 months lags behind the Healthy People 2010 goal of 50%. The objective of this study was to evaluate associations between breastfeeding discontinuation at 2 and 12 weeks postpartum and clinician support, maternal physical and mental health status, workplace issues, and other factors amenable to intervention. METHODS: A prospective cohort study was conducted of low-risk mothers and infants who were in a health maintenance organization and enrolled in a randomized, controlled trial of home visits. Mothers were interviewed in person at 1 to 2 days postpartum and by telephone at 2 and 12 weeks. Logistic regression modeling was performed to assess the independent effects of the predictors of interest, adjusting for sociodemographic and other confounding variables. RESULTS: Of the 1163 mother-newborn pairs in the cohort, 1007 (87%) initiated breastfeeding, 872 (75%) were breastfeeding at the 2-week interview, and 646 (55%) were breastfeeding at the 12-week interview. In the final multivariate models, breastfeeding discontinuation at 2 weeks was associated with lack of confidence in ability to breastfeed at the 1- to 2-day interview (odds ratio [OR]: 2.8; 95% confidence interval [CI]: 1.02-7.6), early breastfeeding problems (OR: 1.5; 95% CI: 1.1-1.97), Asian race/ethnicity (OR: 2.6; 95% CI: 1.1-5.7), and lower maternal education (OR: 1.5; 95% CI: 1.2-1.9). Mothers were much less likely to discontinue breastfeeding at 12 weeks postpartum if they reported (during the 12-week interview) having received encouragement from their clinician to breastfeed (OR: 0.6; 95% CI: 0.4-0.8). Breastfeeding discontinuation at 12 weeks was also associated with demographic factors and maternal depressive symptoms (OR: 1.18; 95% CI: 1.01-1.37) and returning to work or school by 12 weeks postpartum (OR: 2.4; 95% CI: 1.8-3.3). CONCLUSIONS: Our results indicate that support from clinicians and maternal depressive symptoms are associated with breastfeeding duration. Attention to these issues may help to promote breastfeeding continuation among mothers who initiate. Policies to enhance scheduling flexibility and privacy for breastfeeding mothers at work or school may also be important, given the elevated risk of discontinuation associated with return to work or school.

- Taylor D. Unnatural eye injuries. *Trans Med Soc Lond* 2001-2002; 118:43-53.
- Taylor JS. The story catches you and you fall down: tragedy, ethnography, and "cultural competence". *Med Anthropol Q* 2003; 17(2):159-81. Abstract: Anne Fadiman's *The Spirit Catches You and You Fall Down: A Hmong Child, Her American Doctors, and the Collision of Two Cultures* (Noonday Press, 1997) is widely used in "cultural competence" efforts within U.S. medical school curricula. This article addresses the relationship between theory, narrative form, and teaching through a close critical reading of that book that is informed by theories of tragedy and ethnographies of medicine. I argue that *The Spirit Catches You* is so influential as ethnography because it is so moving as a story; it is so moving as a story because it works so well as tragedy; and it works so well as tragedy precisely because of the static, reified, essentialist understanding of "culture" from which it proceeds. If professional anthropologists wish our own best work to speak to "apparitions of culture" within medicine and other "cultures of no culture," I suggest that we must find compelling new narrative forms in which to convey more complex understandings of "culture."
- Taylor KI. Understanding communities today: using matching needs and services to assess community needs and design community-based services. *Child Welfare* 2005; 84(2):251-64. Abstract: Matching Needs and Services (MNS) is a practice tool intended to help people who work with vulnerable children use rigorously assembled information on needs as a guide to design, implement, and evaluate more-effective services. To do this, MNS focuses on needs but links them to outcomes and thresholds before dealing with the services to achieve those outcomes.

- Tcheremissine OV, Lane SD, Lieving LM, Rhoades HM, Nouvion S, Cherek DR. Individual differences in aggressive responding to intravenous flumazenil administration in adult male parolees. *J Psychopharmacol* 2005; 19(6):640-6. Abstract: Nonhuman and human studies have shown that benzodiazepine (BZD) receptor agonists can modify aggressive behaviour. However, it is unknown whether flumazenil, a BZD receptor antagonist, enhances or inhibits aggressive behaviour. The present study was designed to investigate the effects of acute administrations of flumazenil on aggressive responding in adult humans. Six adult males with histories of childhood conduct disorder (DSM IV R) participated in experimental sessions. Aggression was measured using the Point Subtraction Aggression Paradigm (PSAP);

Cherek 1992), which provided subjects with aggressive and monetary-reinforced response options. Acute doses of flumazenil (2 and 3mg) did not produce statistically significant changes in either monetary-reinforced responding or aggressive responding. The analysis of individual subjects data revealed that aggressive responses varied across subjects. The results are discussed in terms of individual differences based on the previous history of BZD abuse. Additional laboratory research is needed to better clarify the behavioural mechanisms by which BZD receptor antagonists modify human aggressive responding.

Mediation in the context of a moderated prevention effect for children of divorce. *J Consult Clin Psychol* 2004; 72(4):617-24. Abstract: This study presents a reanalysis of data from an effective preventive intervention for children from divorced families to test mediation of program effects. The study involved 157 children, age 9-12 years, who were randomly assigned to a parenting program or a literature control condition. Program effects to reduce posttest internalizing problems were mediated through improvement in mother-child relationship quality. Program effects to reduce externalizing problems at posttest and 6 months were mediated through improvement in posttest parental methods of discipline and mother-child relationship quality. The study also describes a new methodology to test mediation of Program x Baseline Status interactions. Analyses demonstrate mediation effects primarily for children who began the program with poorer scores on discipline, mother-child relationship quality, and externalizing problems.

Teklehaimanot K. United Kingdom: denying children's milk allowance to HIV-positive mother seeking asylum is discriminatory. *Can HIV AIDS Policy Law Rev* 2003; 8(1):73-4. Abstract: In July 2002, the High Court of Justice found that, in denying the milk allowance, the Home Office had failed to realize the real risk that the mother might breastfeed her daughter and that the daughter might be infected with HIV. The Court also ruled that the Home Office's action was discriminatory under Article 14 of the European Convention on Human Rights and Fundamental Freedoms.

Temrin H, Nordlund J, Sterner H. Are stepchildren over-represented as victims of lethal parental violence in Sweden? *Proc Biol Sci* 2004; 271 Suppl 3:S124-6. Abstract: Evolutionary psychologists have suggested that stepchildren should be over-represented as victims of lethal parental violence compared with children living with their two genetic parents, because of relatively more lapses in parental solicitude among stepparents. In our study, using data over a period of 35 years in Sweden (1965-1999), there was no overall

over-representation of stepchildren as victims. For very young stepchildren there was a tendency for over-representation. In families with both stepchildren and children genetically related to the offender, genetic children tended to be more likely to be victims.

Tenenbaum T, Hasan C, Kramm CM *et al.* Oncological management of pediatric cancer patients belonging to Jehovah's Witnesses: a two-institutional experience report. *Onkologie* 2004; 27(2):131-7. Abstract: OBJECTIVES: Aim of this study was to analyze the feasibility of oncological treatment in pediatric patients belonging to Jehovah's Witnesses and to describe the changing policy in performing transfusions and supportive care measures at two German pediatric cancer institutions. PATIENTS AND METHODS: Over a period of 16 years 21 treatments according to the current cooperative protocols were performed in 14 children of Jehovah's Witnesses. Various hematological supportive care measures such as supplementation with iron, human erythropoietin, interleukin 11, granulocyte colony-stimulating factor and autologous or allogeneic stem cell rescue had been applied. For comparison matched pairs treated in our hospitals not belonging to Jehovah's Witnesses and 50 pediatric and adult oncological patients belonging to Jehovah's Witnesses reviewed from the international literature were analyzed with respect to transfusions and outcome. RESULTS: So far, 9 of 14 children are surviving 16-195 months (median 26 months). During the primary therapy they received markedly less transfusions than the control cohort (-39,1% red blood cell transfusions and -37,5% platelet transfusions). The review of 50 reported cases showed that oncological therapy can also be successfully performed with a restricted transfusion regimen in children and particularly in adults. CONCLUSION: Pediatric cancer patients belonging to Jehovah's Witnesses can be treated similarly to other patients. A restrictive transfusion policy and the broad application of hematopoietic supportive care measures may reduce transfusions. This treatment policy and a continuous collaboration with the Hospital Liaison Committee for Jehovah's Witnesses appears to create an oncological treatment situation with a high compliance of patients and parents where court orders may not be necessary.

Teplin LA, McClelland GM, Abram KM, Mileusnic D. Early violent death among delinquent youth: a prospective longitudinal study. *Pediatrics* 2005; 115(6):1586-93. Abstract: OBJECTIVE: Youth processed in the juvenile justice system are at great risk for early violent death. Groups at greatest risk, ie, racial/ethnic minorities, male youth, and urban youth, are overrepresented in the juvenile justice system. We compared mortality rates for delinquent youth with those for the general population, controlling for differences in gender, race/ethnicity, and age. METHODS: This prospective longitudinal study

examined mortality rates among 1829 youth (1172 male and 657 female) enrolled in the Northwestern Juvenile Project, a study of health needs and outcomes of delinquent youth. Participants, 10 to 18 years of age, were sampled randomly from intake at the Cook County Juvenile Temporary Detention Center in Chicago, Illinois, between 1995 and 1998. The sample was stratified according to gender, race/ethnicity (African American, non-Hispanic white, Hispanic, or other), age (10-13 or > or =14 years), and legal status (processed as a juvenile or as an adult), to obtain enough participants for examination of key subgroups. The sample included 1005 African American (54.9%), 296 non-Hispanic white (16.2%), 524 Hispanic (28.17%), and 4 other-race/ethnicity (0.2%) subjects. The mean age at enrollment was 14.9 years (median age: 15 years). The refusal rate was 4.2%. As of March 31, 2004, we had monitored participants for 0.5 to 8.4 years (mean: 7.1 years; median: 7.2 years; interquartile range: 6.5-7.8 years); the aggregate exposure for all participants was 12944 person-years. Data on deaths and causes of death were obtained from family reports or records and were then verified by the local medical examiner or the National Death Index. For comparisons of mortality rates for delinquents and the general population, all data were weighted according to the racial/ethnic, gender, and age characteristics of the detention center; these weighted standardized populations were used to calculate reported percentages and mortality ratios. We calculated mortality ratios by comparing our sample's mortality rates with those for the general population of Cook County, controlling for differences in gender, race/ethnicity, and age. **RESULTS:** Sixty-five youth died during the follow-up period. All deaths were from external causes. As determined by using the weighted percentages to estimate causes of death, 95.5% of deaths were homicides or legal interventions (90.1% homicides and 5.4% legal interventions), 1.1% of all deaths were suicides, 1.3% were from motor vehicle accidents, 0.5% were from other accidents, and 1.6% were from other external causes. Among homicides, 93.0% were from gunshot wounds. The overall mortality rate was >4 times the general-population rate. The mortality rate among female youth was nearly 8 times the general-population rate. African American male youth had the highest mortality rate (887 deaths per 100000 person-years). **CONCLUSIONS:** Early violent death among delinquent and general-population youth affects racial/ethnic minorities disproportionately and should be addressed as are other health disparities. Future studies should identify the most promising modifiable risk factors and preventive interventions, explore the causes of death among delinquent female youth, and examine whether minority youth express suicidal intent by putting themselves at risk for homicide.

Teram E, Schachter CL, Stalker CA. The case for integrating grounded theory and participatory action research:

empowering clients to inform professional practice. *Qual Health Res* 2005; 15(8):1129-40. Abstract: Grounded theory and participatory action research methods are distinct approaches to qualitative inquiry. Although grounded theory has been conceptualized in constructivist terms, it has elements of positivist thinking with an image of neutral search for objective truth through rigorous data collection and analysis. Participatory action research is based on a critique of this image and calls for more inclusive research processes. It questions the possibility of objective social sciences and aspires to engage people actively in all stages of generating knowledge. The authors applied both approaches in a project designed to explore the experiences of female survivors of childhood sexual abuse with physical therapy and subsequently develop a handbook on sensitive practice for clinicians that takes into consideration the needs and perspectives of these clients. Building on this experience, they argue that the integration of grounded theory and participatory action research can empower clients to inform professional practice.

Tessa C, Mascalchi M, Matteucci L, Gavazzi C, Domenici R. Permanent brain damage following acute clonidine poisoning in Munchausen by proxy. *Neuropediatrics* 2001; 32(2):90-2.

Abstract: A child presented with recurrent episodes of lethargia for which he underwent several hospital admissions and investigations. A further episode culminated in respiratory arrest and hypoxic ischemic encephalopathy with permanent mental regression. Eighteen months later the mother was discovered while providing clonidine pills to the child; the mother appears to feature a Munchausen syndrome by proxy.

Teusch R. Substance abuse as a symptom of childhood sexual abuse. *Psychiatr Serv* 2001; 52(11):1530-2.

Abstract: The recovery process of a 37-year-old woman with adult onset posttraumatic stress disorder (PTSD) is presented. The patient had suffered childhood sexual abuse and had self-medicated for many years with drugs and alcohol to maintain the dissociation of memories of abuse and to facilitate interpersonal functioning. Upon onset of PTSD, the patient's substance abuse became a full-blown addiction that was highly resistant to treatment. It became evident that her substance abuse symbolically repeated her traumatization. In reexperiencing the affects associated with her earlier trauma (despair, denial, shame, and helplessness) as part of her substance abuse and in the transference, the patient was able to gain mastery over these affects and, subsequently, was able to achieve a stable recovery from both illnesses.

Thabet AA, Abed Y, Vostanis P. Comorbidity of PTSD and depression among refugee children during war conflict. *J Child Psychol Psychiatry* 2004; 45(3):533-42.

**Abstract:** **BACKGROUND:** We examined the prevalence and nature of comorbid post-traumatic stress reactions and depressive symptoms, and the impact of exposure to traumatic events on both types of psychopathology, among Palestinian children during war conflict in the region. **METHODS:** The 403 children aged 9-15 years, who lived in four refugee camps, were assessed by completing the Gaza Traumatic Events Checklist, the Child Post Traumatic Stress Reaction Index (CPTSD-RI), and the Short Mood and Feelings Questionnaire (MFQ). **RESULTS:** Children reported experiencing a wide range of traumatic events, both direct experience of violence and through the media. CPTSD-RI and MFQ scores were significantly correlated. Both CPTSD-RI and MFQ scores were independently predicted by the number of experienced traumatic events, and this association remained after adjusting for socioeconomic variables. Exposure to traumatic events strongly predicted MFQ scores while controlling for CPTSD-RI scores. In contrast, the association between traumatic events and CPTSD-RI scores, while controlling for MFQ scores, was weak. The CPTSD-RI items whose frequency was significantly associated with total MFQ scores were: sleep disturbance, somatic complaints, constricted affect, impulse control, and difficulties in concentration. However, not all remaining CPTSD-RI items were significantly associated with exposure to traumatic events, thus raising the possibility that the association between depression and PTSD was due in part to symptom overlap. **CONCLUSIONS:** Children living in war zones are at high risk of suffering from PTSD and depressive disorders. Exposure to trauma was not found to have a unique association with PTSD. The relationship between PTSD and depressive symptomatology requires further investigation.

Thabet AA, Abed Y, Vostanis P. Emotional problems in Palestinian children living in a war zone: a cross-sectional study. *Lancet* 2002; 359(9320):1801-4. **Abstract:** **BACKGROUND:** Children living in war zones are at high risk of developing post-traumatic stress and other emotional disorders, but little is known about the effect of traumatic events during war. We aimed to assess the nature and severity of emotional problems in Palestinian children whose homes had been bombarded and demolished during the crisis in Palestine, compared with children living in other parts of the Gaza strip. **METHODS:** 91 children exposed to home bombardment and demolition during Al Aqsa Intifada and 89 controls who had been exposed to other types of traumatic events related to political violence completed self-report measures of post-traumatic stress, anxiety, and fears. **FINDINGS:** Significantly more children exposed to bombardment and home demolition reported symptoms of post-traumatic stress ( $p=0.0008$ ) and fear ( $p=0.002$ ) than controls. 54 (59%) of 91 exposed children and 22 (25%) of 89 controls reported post-traumatic stress reactions of clinical importance. Exposure to bombardment was the

strongest socioeconomic predictor of post-traumatic stress reactions (odds ratio 0.25 [95% CI 0.12-0.53],  $p=0.0008$ ). By contrast, children exposed to other events, mainly through the media and adults, reported more anticipatory anxiety and cognitive expressions of distress ( $p=0.001$ ) than children who were directly exposed. **INTERPRETATION:** Children living in war zones can express acute distress from various traumatic events through emotional problems that are not usually recognised. Health professionals and other agencies coming in contact with children who have been affected by war and political violence need to be trained in detection and treatment of such presentations.

Thadani PV. The intersection of stress, drug abuse and development. *Psychoneuroendocrinology* 2002; 27(1-2):221-30.

**Abstract:** Use or abuse of licit and illicit substances is often associated with environmental stress. Current clinical evidence clearly demonstrates neurobehavioral, somatic growth and developmental deficits in children born to drug-using mothers. However, the effects of environmental stress and its interaction with prenatal drug exposure on a child's development is unknown. Studies in pregnant animals under controlled conditions show drug-induced long-term alterations in brain structures and functions of the offspring. These cytoarchitecture alterations in the brain are often associated with perturbations in neurotransmitter systems that are intimately involved in the regulation of the stress responses. Similar abnormalities have been observed in the brains of animals exposed to other adverse exogenous (e.g., environmental stress) and/or endogenous (e.g., glucocorticoids) experiences during early life. The goal of this article is to: (1) provide evidence and a perspective that common neural systems are influenced during development both by perinatal drug exposure and early stress exposure; and (2) identify gaps and encourage new research examining the effects of early stress and perinatal drug exposure, in animal models, that would elucidate how stress- and drug-induced perturbations in neural systems influence later vulnerability to abused drugs in adult offspring.

Therrell BL Jr. U.S. newborn screening policy dilemmas for the twenty-first century. *Mol Genet Metab* 2001; 74(1-2):64-74.

**Abstract:** Newborn screening has traditionally referred to biochemical testing for inherited disorders, generally metabolic in origin, that are usually correctable by dietary or drug interventions. As new tests have been developed, state public health newborn screening systems have slowly evolved without the benefit of national policies. Thus, newborn screening program changes, when viewed nationally, have been uncoordinated. The net result has been unequally applied mandated screening and, consequently, unequal availability of related public health disease prevention

services. Technological advances in laboratory testing over the past 10 years have resulted in limited program changes in some state newborn screening systems, and even greater program disparities. A recent Newborn Screening Task Force identified numerous issues of concern and proposed elements for a plan of action involving public health programs, healthcare providers, and consumers. This minireview details past policy history in newborn screening and identifies some of the current issues confronting programs as they seek to move ahead with the technologies and medical treatments for the twenty-first century.

Thibault KL. Some pitfalls of computer modeling. *Arch Pediatr Adolesc Med* 2002; 156(3):296-7.

Tholcken M, Lehna C. Advanced practice nurses as faculty. *MCN Am J Matern Child Nurs* 2001; 26(6):323-7. Abstract: This article details a program through which two child health faculty members who are advanced practice nurses (APNs) combined practice with teaching undergraduate students in a community-based clinical experience on nursing case management. A collaborative agreement between a university-based Children's Special Services Team (CSST) and school of nursing faculty was developed to extend services into the home communities of children with special healthcare needs. Senior students made visits to the homes of the team's clients, conducted assessments, interacted with families, and provided additional care. The team, which included physicians, nurses, a social worker, and therapists (occupational and physical) identified children and families who would benefit from home visits by students nurses who were directed by APNs. Both service and educational goals were accomplished by this community-based case-management experience. The children and their families received additional care from multiple healthcare providers. Students practiced components of community-based case management, and the CSST obtained vital information about their clients' living environments.

Thomas C. Guthrie test samples: is the problem solved? *N Z Bioeth J* 2004; 5(2):25-33. Notes: GENERAL NOTE: KIE: 24 refs.  
GENERAL NOTE: KIE: KIE Bib: genetic research; genetic screening; mass screening  
Abstract: Most babies born in New Zealand have a blood sample taken shortly after birth for the purposes of certain screening tests. The samples are retained indefinitely. This paper considers whether such samples are the property of the child and whether the

present changes in the Health (National Cervical Screening Programme) Amendment Bill and the Code of Health and Disability Services Consumers' Rights of 1996 are sufficient to resolve the issues. The paper expresses concern about the delegation of decision-making in this area to ethics committees.

Thomas KA. Safety: when infants and parents are research subjects. *J Perinat Neonatal Nurs* 2005; 19(1):52-8. Abstract: Patient safety is a central concern in nursing. Unlike other areas of patient safety, safety in research is particularly important because research is not part of standard care and participation is voluntary. Issues related to safety in research are especially pertinent to high-risk infants, because of the nature of parental (or legal guardian) consent and because children are considered a vulnerable group requiring special protection from research risks. Nurses must be aware of safety in research whether independently conducting research, employed by a research project, or caring for patients who are research subjects. This article reviews safety issues and policies, processes, and ethical guidelines designed to protect infants and children who are research subjects.

Thomas M, Karmiloff-Smith A. Are developmental disorders like cases of adult brain damage? Implications from connectionist modelling. *Behav Brain Sci* 2002; 25(6):727-50; discussion 750-87. Abstract: It is often assumed that similar domain-specific behavioural impairments found in cases of adult brain damage and developmental disorders correspond to similar underlying causes, and can serve as convergent evidence for the modular structure of the normal adult cognitive system. We argue that this correspondence is contingent on an unsupported assumption that atypical development can produce selective deficits while the rest of the system develops normally (Residual Normality), and that this assumption tends to bias data collection in the field. Based on a review of connectionist models of acquired and developmental disorders in the domains of reading and past tense, as well as on new simulations, we explore the computational viability of Residual Normality and the potential role of development in producing behavioural deficits. Simulations demonstrate that damage to a developmental model can produce very different effects depending on whether it occurs prior to or following the training process. Because developmental disorders typically involve damage prior to learning, we conclude that the developmental process is a key component of the explanation of endstate impairments in such disorders. Further simulations demonstrate that in simple connectionist learning systems, the assumption of Residual Normality is undermined by processes of compensation or alteration elsewhere in the system. We outline the precise computational conditions required for Residual Normality to hold in development, and suggest that in many cases it is an

unlikely hypothesis. We conclude that in developmental disorders, inferences from behavioural deficits to underlying structure crucially depend on developmental conditions, and that the process of ontogenetic development cannot be ignored in constructing models of developmental disorders.

Thomas R. School-based programmes for preventing smoking. *Cochrane Database Syst Rev* 2002; (4):CD001293.

**Abstract:** **BACKGROUND:** Smoking rates in adolescents are rising. Helping young people to avoid starting smoking is a widely endorsed goal of public health, but there is uncertainty about how to do this. Schools provide a route for communicating with a large proportion of young people, and school-based programmes for smoking prevention have been widely developed and evaluated. **OBJECTIVES:** To review all randomised controlled trials of behavioural interventions in schools to prevent children (aged 5 to12) and adolescents (aged 13 to18) starting smoking. **SEARCH STRATEGY:** We searched The Cochrane Controlled Trials and Tobacco Review group registers, MEDLINE, EMBASE, PsycInfo, ERIC, CINAHL, Health Star, Dissertation Abstracts and studies identified in the bibliographies of articles. Individual MEDLINE searches were made for 133 authors who had undertaken randomised controlled trials in this area. **SELECTION CRITERIA:** Types of studies: those in which individual students, classes, schools, or school districts were randomised to the intervention or control groups and followed for at least six months. Types of participants: Children (aged 5 to12) or adolescents (aged 13 to18) in school settings. Types of interventions: Classroom programmes or curricula, including those with associated family and community interventions, intended to deter use of tobacco. We included programmes or curricula that provided information, those that used social influences approaches, those that taught generic social competence, and those that included interventions beyond the school into the community. We included programmes with a drug or alcohol focus if outcomes for tobacco use were reported. Types of outcome measures: Prevalence of non-smoking at follow-up among those not smoking at baseline. We did not require biochemical validation of self-reported tobacco use for study inclusion. **DATA COLLECTION AND ANALYSIS:** We assessed whether identified citations were randomised controlled trials. We assessed the quality of design and execution, and abstracted outcome data. Because of the marked heterogeneity of design and outcomes, we did not perform a meta-analysis. We synthesised the data using narrative systematic review. We grouped studies by intervention method (information; social competence; social influences; combined social influences/social competence and multi-modal programmes). Within each category, we placed them into three groups according to validity using quality criteria for reported

study design. **MAIN RESULTS:** Of the 76 randomised controlled trials identified, we classified 16 as category one (most valid). There were no category one studies of information giving alone. There were fifteen category one studies of social influences interventions. Of these, eight showed some positive effect of intervention on smoking prevalence, and seven failed to detect an effect on smoking prevalence. The largest and most rigorous study, the Hutchinson Smoking Prevention Project, found no long-term effect of an intensive 8-year programme on smoking behaviour. There was a lack of high quality evidence about the effectiveness of combinations of social influences and social competence approaches. There was limited evidence about the effectiveness of multi-modal approaches including community initiatives. **REVIEWER'S CONCLUSIONS:** There is no rigorous test of the effects of information giving about smoking. There are well-conducted randomised controlled trials to test the effects of social influences interventions: in half of the group of best quality studies those in the intervention group smoke less than those in the control, but many studies showed no effect of the intervention. There is a lack of high-quality evidence about the effectiveness of combinations of social influences and social competence interventions, and of multi-modal programmes that include community interventions.

Thomas T. Covert video surveillance: an appraisal of the UKCC Position Statement. *Paediatr Nurs* 2001; 13(4):15-7.

Thompson A, Hollis C, Dagger DR. Authoritarian parenting attitudes as a risk for conduct problems Results from a British national cohort study. *Eur Child Adolesc Psychiatry* 2003; 12(2):84-91. **Abstract:** This study examines the associations, and possible causal relationship, between mothers' authoritarian attitudes to discipline and child behaviour using cross-sectional and prospective data from a large population sample surveyed in the 1970 British Cohort Study. Results show a clear linear relationship between the degree of maternal approval of authoritarian child-rearing attitudes and the rates of conduct problems at age 5 and age 10. This association is independent of the confounding effects of socio-economic status and maternal psychological distress. Maternal authoritarian attitudes independently predicted the development of conduct problems 5 years later at age 10. The results of this longitudinal study suggest that authoritarian parenting attitudes expressed by mothers may be of significance in the development of conduct problems.

Thompson DG. Safe sleep practices for hospitalized infants. *Pediatr Nurs* 2005; 31(5):400-3, 409. **Abstract:** Guidelines were established over 10 years ago by professional and government agencies that have dramatically changed the practice of infant sleep positioning. Although these guidelines mainly focus

care on the newborn and infant in their home by a parent, guardian or caregiver, hospital staff need to examine their compliance with these guidelines. The most controversial aspect of the "Back to Sleep" guidelines for the hospital setting is the parent and infant sharing a bed. Although parents may choose to sleep with their infant at home, the need for monitoring, ongoing assessment and care as well as the risk of entrapment or injury should be a priority in the delivery of optimal patient care in the hospital setting. The need for a policy was identified and developed by a multidisciplinary task force focusing on the physiological, behavioral and cultural aspects of cosleeping.

Thompson JB. International policies for achieving safe motherhood: women's lives in the balance. *Health Care Women Int* 2005; 26(6):472-83. Abstract: Every minute of every day somewhere in the world one woman dies during pregnancy or childbirth and eight newborns die, which is a great loss to families and to societies. Nearly two decades of global efforts to promote safe motherhood and newborn health have led to several conclusions as to why these unnecessary deaths of women and newborns continue, especially in the developing world. Healthy women are needed for healthy newborns and families, yet attention to the health of women, especially during childbearing, has received minimal or no attention at country and local levels where policies seem to ignore the value of the girl-child, women and newborns. One of the most important interventions proven to promote safe or healthy pregnancy for women and their newborns is the availability of skilled care--the combination of an accredited health professional with midwifery skills working in an well-equipped environment at the community level, supported by the political will needed to save the lives of mothers and babies. Yet skilled care is missing from nearly half of the world's women. This article describes the reasons for the continuing high rates of maternal and newborn deaths, key lessons learned about how to prevent such deaths based on the best available evidence, and the need for evidence-based policies directed at achieving safe motherhood for each woman who becomes pregnant and for her newborn.

Thompson KM, Haninger K. Violence in E-rated video games. *JAMA* 2001; 286(5):591-8. Abstract: CONTEXT: Children's exposure to violence, alcohol, tobacco and other substances, and sexual messages in the media are a source of public health concern; however, content in video games commonly played by children has not been quantified. OBJECTIVES: To quantify and characterize the depiction of violence, alcohol, tobacco and other substances, and sex in video games rated E (for "Everyone"), analogous to the G rating of films, which suggests suitability for all audiences. DESIGN: We created a database of all existing E-rated video games

available for rent or sale in the United States by April 1, 2001, to identify the distribution of games by genre and to characterize the distribution of content descriptors associated with these games. We played and assessed the content of a convenience sample of 55 E-rated video games released for major home video game consoles between 1985 and 2000. MAIN OUTCOME MEASURES: Game genre; duration of violence; number of fatalities; types of weapons used; whether injuring characters or destroying objects is rewarded or is required to advance in the game; depiction of alcohol, tobacco and other substances; and sexual content. RESULTS: Based on analysis of the 672 current E-rated video games played on home consoles, 77% were in sports, racing, or action genres and 57% did not receive any content descriptors. We found that 35 of the 55 games we played (64%) involved intentional violence for an average of 30.7% of game play (range, 1.5%-91.2%), and we noted significant differences in the amount of violence among game genres. Injuring characters was rewarded or required for advancement in 33 games (60%). The presence of any content descriptor for violence (n = 23 games) was significantly correlated with the presence of intentional violence in the game (at a 5% significance level based on a 2-sided Wilcoxon rank-sum test,  $t(53) = 2.59$ ). Notably, 14 of 32 games (44%) that did not receive a content descriptor for violence contained acts of violence. Action and shooting games led to the largest numbers of deaths from violent acts, and we found a significant correlation between the proportion of violent game play and the number of deaths per minute of play. We noted potentially objectionable sexual content in 2 games and the presence of alcohol in 1 game. CONCLUSIONS: Content analysis suggests a significant amount of violence in some E-rated video games. The content descriptors provide some information to parents and should be used along with the rating, but the game's genre also appears to play a role in the amount of violent play. Physicians and parents should understand that popular E-rated video games may be a source of exposure to violence and other unexpected content for children and that games may reward the players for violent actions.

Thompson RS, Lawrence DM, Huebner CE, Johnston BD. Expanding developmental and behavioral services for newborns in primary care: implications of the findings. *Am J Prev Med* 2004; 26(4):367-71. Abstract: BACKGROUND: In two other papers in this issue, the rationale, development, implementation, experimental design, approach to evaluation, and early results of a program to deliver developmental and behavioral services to all infants in primary care practice were described. Positive effects were seen for parental satisfaction, including decreased disenrollment, provider satisfaction, parenting practices, and health outcomes. METHODS: In the present article, the results are reviewed and

implications of our findings for the delivery of care, families, healthcare systems, and further research are discussed. **RESULTS:** Findings that have broad implications are as follows: (1) developmental and behavioral services can be delivered successfully in practice using dedicated professionals to deliver and integrate services; (2) the "planned care model" was useful in program implementation for making "the right thing to do, the easy thing to do"; (3) the added focus on satisfaction and cost helps to develop the "business case" for broad scale implementation; (4) bonding of parents to organizations has marketing implications; (5) the program provides positive effects for all parents, not just high-risk parents; and (6) several research questions emerge, including persistence of effects on health outcomes, costs, and utilization. **CONCLUSIONS:** The authors conclude that study results have implications for preventive services, families, child healthcare in office practice, healthcare systems, and healthcare policy. In this ongoing study, examination of intervention effects at 30 months of age should be informative. Further research is warranted as it remains to be seen whether or not these interventions can become viable ongoing programs.

Thompson TR, Belsito DV. Regional variation in prevalence and etiology of allergic contact dermatitis. *Am J Contact Dermat* 2002; 13(4):177-82. Abstract: **BACKGROUND:** The 1994-1996 North American Contact Dermatitis Group (NACDG) patch test results were the first, since the inception of the NACDG in 1970, to include results from a medium-sized metropolitan city in the Midwest. **OBJECTIVE:** The aim of this study was to determine whether the causative allergens of allergic contact dermatitis (ACD) in the Midwest differ from those in other regions of the United States and, if so, whether occupational or other factors account for the observed differences. **METHODS:** Retrospective analyses of patch test data collected at the University of Kansas Medical Center (Kansas City, KS) were compared with the data collected by the other NACDG centers. **RESULTS:** Patients in Kansas City were statistically more likely to react to potassium dichromate, formaldehyde and its releasers, methylchloroisothiazolinone/methylisothiazolinone (MCI/MI), and glutaraldehyde. Occupational exposures to chromium and formaldehyde were increased significantly among patients from Kansas City, although the percentages of the local population engaged in these occupations did not differ from those in other NACDG cities. Equal percentages of workers in Kansas City and nationally had occupationally related allergy to glutaraldehyde, although the overall rate of glutaraldehyde was higher among patients from Kansas City. Most cases of relevant allergy to MCI/MI were cosmetically induced both in Kansas City and nationally. **CONCLUSIONS:** The current findings show significant regional differences in causal allergens. The increased percentages of patients seen

with ACD to formaldehyde, formaldehyde-releasing agents, and potassium dichromate in Kansas City were likely caused by the referral of greater numbers of work-related cases. However, occupationally acquired ACD to MCI/MI and glutaraldehyde were not more frequent in Kansas City than nationally, suggesting that other factors might be operative. Although awareness of national trends is important, dermatologists must be cognizant of regional variations in allergen sources within their communities and referral networks.

Thomson CC, Roberts K, Curran A, Ryan L, Wright RJ. Caretaker-child concordance for child's exposure to violence in a preadolescent inner-city population. *Arch Pediatr Adolesc Med* 2002; 156(8):818-23. Abstract: **BACKGROUND:** Effective screening for exposure to violence (ETV) in the pediatric setting depends on informant reliability and recognition of patients at increased risk. Pediatricians screening for children's ETV often rely on parent reporting. **HYPOTHESIS:** That there would be poor caretaker-child concordance given that children would report events occurring outside the home not witnessed by the caretaker and that ETV would be higher among immigrant families. **OBJECTIVES:** To examine concordance between caretaker and child self-report of the child's ETV in a preadolescent population and to explore factors related to increased risk. **DESIGN:** Community-based survey. **SETTING:** Urban community health center. **PARTICIPANTS:** One hundred sixty-five caretaker-child pairs. **METHODS:** The ETV was assessed by means of a standardized interview questionnaire on location and frequency of ETV. A Rasch model was used to develop summary scores of ETV (frequency and severity). **RESULTS:** Caretaker-child concordance on reports of child's ETV was poor. The kappa statistics ranged from -0.04 for seeing someone knifed to 0.39 for witnessing a shooting. Children reported ETV more often in their neighborhood or at school, whereas caretakers reported more events near or at home. Univariate predictors of child's self-reported ETV were female sex (beta +/- SE, -10.1 +/- 4.6; P =.03) and caretaker being divorced (beta +/- SE, 12.6 +/- 6.0; P =.04). In multivariate analyses, country of origin predicted child's ETV, adjusting for child's age and sex, and caretaker educational status and marital status. **CONCLUSIONS:** Caretakers and their children have poor agreement on reports of the child's ETV. Intervention strategies around ETV should include assessment of the child independent of caretaker report for preadolescents. Screening may be more effective if pediatricians are aware of factors related to increased risk, including immigration status and caretaker marital status.

Thun-Hohenstein L. [The work of child protection groups in Austria]. *Wien Med Wochenschr* 2005; 155(15-16):365-70. Abstract: **AIM:** To document the number of child protection groups (CPG) in children's hospitals and

paediatric surgeries in Austria. Further, to document detection frequency of abuse syndromes per inpatients per year and structural differences between departments with and without CPGs. **METHODS:** Self-compiled questionnaire was distributed to all pediatric (43) and all pediatric surgery units (7). **RESULTS:** 68% of children's hospitals and 100% of paediatric surgical units had a CPG. Average detection frequency was reported to be 0.8 +/- 0.67% (range, 0-3.5). Distribution of CPG diagnoses is comparable, only sexual abuse was reported more frequently than reported internationally. Departments with CPG have more beds, more personnel, especially more psychosocial workers, and higher detection frequency. **CONCLUSIONS:** Frequency of CPGs is comparable to U.S. and Swiss data. Detection rates are low normal, but in departments without CPG, far below international standards.

Tickle JJ, Sargent JD, Dalton MA, Beach ML, Heatherton TF. Favourite movie stars, their tobacco use in contemporary movies, and its association with adolescent smoking. *Tob Control* 2001; 10(1):16-22. **Abstract:** **OBJECTIVE:** To assess the relation between adolescents' favourite movie stars, the portrayal of tobacco use by those stars in contemporary motion pictures, and adolescent smoking. **DESIGN AND SETTING:** 632 students (sixth to 12th grade, ages 10-19 years) from five rural New England public schools completed a voluntary, self administered survey in October 1996. The survey assessed tobacco use, other variables associated with adolescent smoking, and favourite movie star. In addition, tobacco use by 43 selected movie stars was measured in films between 1994 and 1996. **OUTCOME MEASURES:** Students were categorised into an ordinal five point index (tobacco status) based on their smoking behaviour and their smoking susceptibility: non-susceptible never smokers, susceptible never smokers, non-current experimenters, current experimenters, and smokers. We determined the adjusted cumulative odds of having advanced smoking status based on the amount of on-screen tobacco use by their favourite film star. **RESULTS:** Of the 43 stars, 65% used tobacco at least once, and 42% portrayed smoking as an essential character trait in one or more films. Stars who smoked more than twice in a film were considered smokers. For adolescents whose favourite stars smoked in only one film, the odds of being higher on the smoking index was 0.78 (95% confidence interval (CI) 0.53 to 1.15). For adolescents whose favourite stars smoked in two films, the odds of being higher on the smoking index was 1.5 (95% CI 1.01 to 2.32). For adolescents whose favourite stars smoked in three or more films (Leonardo DiCaprio, Sharon Stone, John Travolta), the odds of being higher on the smoking index was 3.1 (95% CI 1.34 to 7.12). Among never smokers (n = 281), those who chose stars who were smokers in three or more films were much more likely to have favourable attitudes toward smoking (adjusted odds

ratio 16.2, 95% CI 2.3 to 112). **CONCLUSIONS:** Adolescents who choose movie stars who use tobacco on-screen are significantly more likely to have an advanced smoking status and more favourable attitudes toward smoking than adolescents who choose non-smoking stars. This finding supports the proposition that the portrayal of tobacco use in contemporary motion pictures, particularly by stars who are admired by adolescents, contributes to adolescent smoking.

Tiedje LB, Darling-Fisher C. Promoting father-friendly healthcare. *MCN Am J Matern Child Nurs* 2003; 28(6):350-7; quiz 358-9. **Abstract:** Fathers are taking a more active role in their children's lives and healthcare; consequently, healthcare providers need to be more aware of and attentive to fathers in clinical encounters. The literature on healthcare provider inclusion of fathers is sparse. The focus has been mainly on exhortations to include fathers, or has documented treatment of fathers as invisible in healthcare settings. While not overtly hostile to fathers, healthcare providers occasionally marginalize or ignore them. The purpose of this article is to help healthcare providers: (1) become aware of and assess their interactions with fathers and (2) be more intentional in their interactions with them. To that end, this article includes a self-assessment of one's practice, including the following components: introductions, body language, eye contact, obtaining/giving information, and beliefs about the role of fathers. Intentional interactions for developing more father-friendly healthcare are discussed including both small and large changes, guided by the PLISSIT model. Finally, best practices, challenges, issues, and resources related to father inclusion in healthcare are described. The major issue for providers is to no longer question whether to include fathers, but how.

Tien I, Bauchner H, Reece RM. What is the system of care for abused and neglected children in children's institutions? *Pediatrics* 2002; 110(6):1226-31. **Abstract:** **OBJECTIVES:** The objectives of this study were to describe the number of children with suspected abuse or neglect (CAN) cared for in selected children's hospitals, to determine how they are tracked and followed, and to better describe the composition, function, and financial support of child protection teams (CPTs). **METHODS:** A self-administered survey was mailed to child abuse contact leaders at institutions that were members of the National Association of Children's Hospitals and Related Institutions in 2001. Responses from rehabilitation hospitals and those that did not indicate whether a CPT was present were excluded. **RESULTS:** One hundred thirty-four of 157 leaders responded. One hundred twenty-two (91%) met study criteria. Eighty-eight hospitals (72%) had a CPT-54% were pediatric facilities, 59% had >100 beds, and 89% had a pediatric residency. Compared with institutions without a CPT, institutions with a CPT were less likely to be located in the South (28% vs

70%) and more likely to have >200 beds (26% vs 1%), a medical school affiliation (92% vs 74%), and a pediatric residency (98% vs 68%). Sixty-one percent of institutions cared for <300 suspected CAN cases, and 66% had 5 or fewer CAN-associated deaths the previous year. Institutions with a CPT used more comprehensive documentation for CAN, including special CAN forms (55% vs 21%) and photographs (77% vs 53%). They also more commonly referred CAN cases to law enforcement (58% vs 35%) or a CAN clinic for follow-up (52% vs 26%). Fifty-two percent of CPTs had an annual budget of \$500 000 or less. The most common primary source of financial support for CPTs was the hospital (51%), although funding was usually composed of a combination of funds from the hospital, patient fees, and state government. Functions performed by CPTs included consulting on cases of CAN (89%), functioning as a liaison with child protective services (85%), tracking cases of abuse or neglect (70%), providing quality assurance on CAN cases (63%), and filing reports with child protective services (61%). Twenty-four hour consultative coverage was provided by most CPTs (79%), for which 94% provided phone consultation and 81% provided in-person consultation when necessary. CONCLUSIONS: The institutions surveyed cared for many children suspected of abuse and neglect. Thirty-eight percent did >300 evaluations per year. In general, institutions with CPTs provided more comprehensive documentation and follow-up of children suspected of having been abused or neglected than institutions without CPTs. Whether this is associated with better outcomes for children suspected of abuse or neglect is unknown.

Tilley DS, Brackley M. Violent lives of women: critical points for intervention--phase I focus groups. *Perspect Psychiatr Care* 2004; 40(4):157-66, 170. Abstract: PROBLEM: To identify critical developmental periods, experiences, and events in women's lives associated with violence to guide a larger study. METHODS: Two focus groups of 10 women each (N = 20) were conducted to determine the critical times when girls and women might be exposed to violence. FINDINGS: Broad themes in the data were developmental periods, abusers, staying in the relationship, leaving the relationship, parenting, and living with violence. The women in these focus groups clearly identified times of increased risk for violence in their lives: establishing intimate relationships, pregnancy, childrearing years, and times when substance abuse is occurring. CONCLUSIONS: While

clinicians should be vigilant for the presence of domestic violence with all clients, it is important to know when a woman experiences increased risk for violence. The findings indicate a need for education for communities, those who provide care for women and children, and people in whom victims may confide.

Timmermans JP, Hens J, Adriaensen D. Outer submucous plexus: an intrinsic nerve network involved in both secretory and motility processes in the intestine of large mammals and humans. *Anat Rec* 2001; 262(1):71-8.

Abstract: The architecture of the enteric nerve networks in the gastrointestinal tract appears to be more complex in large mammals, including humans, than in small laboratory animals. At least two distinct ganglionic nerve plexuses could be identified in the submucous layer in the digestive tract of large mammals. While functionally and morphologically similar neuron populations are found in the intestinal wall of both small and large mammals, significant differences in their topographical organization and neurochemical features may be present. This short review clearly illustrates that the close and exclusive association, which has been assumed so far between the efferent pathways of the submucous plexus and regulation of intestinal secretion/absorption on the one hand and between the myenteric plexus and regulation of intestinal motility on the other hand, cannot be interpreted that strictly. An attempt has been made to give a brief overview of the current status of the identification of distinct functional enteric neuronal classes in the gastrointestinal tract of large mammals using the pig and human intestine as references, and to compare these data with the more extensive information gathered from the guinea-pig intestine.

Tirosh E, Cohen A, Stein M, Jaffe M. Factors affecting participation in a child development programme. *Int J Rehabil Res* 2001; 24(4):321-4.

Tirosh E, Offer Shechter S, Cohen A, Jaffe M. Attitudes towards corporal punishment and reporting of abuse. *Child Abuse Negl* 2003; 27(8):929-37. Abstract: OBJECTIVES: To assess physicians' attitudes towards corporal punishment in childhood and their subsequent actions regarding the reporting of child abuse. PARTICIPANTS: 107 physicians (95 pediatricians and 12 family practitioners) who work in hospitals and community clinics in northern Israel were interviewed. Of the participants, 16% were new immigrants. PROCEDURE: A structured interview was conducted by one of two pediatric residents. RESULTS: Attitudes towards corporal punishment were not influenced by the physicians' sex or specialty. Corporal punishment was approved by 58% of the physicians. A significant difference in attitudes towards corporal punishment between immigrants and Israeli born physicians was found (p=.004). Family

practitioners and especially senior ones were found significantly less tolerant towards corporal punishment than pediatricians ( $p=.04$ ). While reporting behavior was not found to be associated with parental status and the past experience of the physicians with child abuse, a significant effect of attitudes towards corporal punishment on reporting behavior was found ( $p=.01$ ). CONCLUSIONS: (1) Corporal punishment is still perceived as an acceptable disciplinary act by a significant proportion of physicians responsible for the health care of children in our area. (2) Attitudes towards corporal punishment are different between immigrants and native born Israeli trained doctors and, unexpectedly, pediatricians were more tolerant of corporal punishment than family practitioners.

Titus JC, Dennis ML, White WL, Scott CK, Funk RR. Gender differences in victimization severity and outcomes among adolescents treated for substance abuse. *Child Maltreat* 2003; 8(1):19-35. Abstract: This article uses data from the Global Appraisal of Individual Needs (GAIN) on 214 adolescents entering substance abuse treatment. The goals of the article are to validate the General Victimization Index (GVI), examine its relationship to gender and co-occurring problems, and determine its relationship to outcomes. The GVI includes 15 items on lifetime traumatic events, traumagenic factors, and current worries of victimization. The items fall along a severity dimension ( $\alpha = .88$ ), and evidence was generated to support the construct validity of cutoff scores for interpretation. Girls were significantly more likely than boys to have experienced a variety of victimization incidents. When used as grouping variables, gender and severity of victimization significantly interacted with measures of intake status and were significant predictors of 3-month postdischarge treatment outcomes.

Tkeshelashvili-Kessler A, del Rio C, Nelson K, Tsertsvadze T. The emerging HIV/AIDS epidemic in Georgia. *Int J STD AIDS* 2005; 16(1):61-7. Abstract: The first case of HIV in Georgia was diagnosed in 1989. Through December 2002, a total of 375 cases of HIV infection were reported. However, the World Health Organization estimates that the true number of infections may be closer to 1700. In all, 70% of reported cases are among injection drug users. Based on the UNAIDS classification, Georgia is a 'low-level HIV country' with an HIV prevalence of less than 1% in all groups, including drug users. However, there is a high prevalence of hepatitis B and C, suggesting a significant risk for the spread of HIV. Georgia, a newly independent republic, is experiencing an increase in injection drug use, a rise in sexually transmitted infections and commercial sex trade that create a fertile soil for the potential rapid spread of HIV. However, it is also a country with a unique window of opportunity for limiting the spread of HIV.

Toker A, Urkin J, Bloch Y. Role of a medical students' association in improving the curriculum at a faculty of health sciences. *Med Teach* 2002; 24(6):634-6. Abstract: The Joyce and Irving Goldman School of Medicine, Faculty of Health Sciences at the Ben Gurion University of the Negev encourages students to take part in the development and evaluation of the teaching experience. These special relations between the school and the students contribute not only to changes in the curriculum but also to increased involvement of faculty and students in the community. This article reviews the special relationship between the Faculty of Health Sciences and its medical students through the Medical Students Association (ASRN). During the last decade, BGU medical students have initiated innovative programmes some of which have recently become integrated into the curriculum. These include: prevention of sexual violence among youth, decreasing white-coat fear in small children ('Teddy Bear hospital') and participation in home-hospice activities. By encouraging students to become equal partners in faculty development and rejecting the traditional paternalistic mode of teacher-student relationships, the faculty has created an improved learning experience, and increased student motivation and levels of communication between the teachers and the future clinicians.

Tomatis S, Bono A, Bartoli C *et al.* Automated melanoma detection: multispectral imaging and neural network approach for classification. *Med Phys* 2003; 30(2):212-21. Abstract: Our aim in the present research is to investigate the diagnostic performance of artificial neural networks (ANNs) applied to multispectral images of cutaneous pigmented skin lesions as well as to compare this approach to a standard traditional linear classification method, such as discriminant function analysis. This study involves a series of 534 patients with 573 cutaneous pigmented lesions (132 melanomas and 441 nonmelanoma lesions). Each lesion was analyzed by a telespectrophotometric system (TS) in vivo, before surgery. The system is able to acquire a set of 17 images at selected wavelengths from 400 to 1040 nm. For each wavelength, five lesion descriptors were extracted, related to the criteria of the ABCD (for asymmetry, border, color, and dimension) clinical guide for melanoma diagnosis. These variables were first reduced in dimension by the use of factor analysis techniques and then used as input data in an ANN. Multivariate discriminant analysis (MDA) was also performed on the same dataset. The whole dataset

was split into two independent groups: i.e., train (the first 400 cases, 95 melanomas) and verification set (last 173 cases, 37 melanomas). Factor analysis was able to summarize the data structure into ten variables, accounting for at least 90% of the original parameters variance. After proper training, the ANN was able to classify the population with 80% sensitivity, 72% specificity, and 78% sensitivity, 76% specificity for the train and validation set, respectively. Following ROC analysis, area under curve (AUC) was 0.852 (train) and 0.847 (verify). Sensitivity and specificity values obtained by the standard discriminant analysis classifier resulted in a figure of 80% sensitivity, 60% specificity and 76% sensitivity, 57% specificity for the train and validation set, respectively. AUC for MDA was 0.810 and 0.764 for the train and verify set, respectively. Classification results were significantly different between the two methods both for diagnostic scores and model stability, which was worse for MDA.

Tomatis S, Carrara M, Bono A *et al.* Automated melanoma detection with a novel multispectral imaging system: results of a prospective study. *Phys Med Biol* 2005; 50(8):1675-87.

Abstract: The aim of this research was to evaluate the performance of a new spectroscopic system in the diagnosis of melanoma. This study involves a consecutive series of 1278 patients with 1391 cutaneous pigmented lesions including 184 melanomas. In an attempt to approach the 'real world' of lesion population, a further set of 1022 not excised clinically reassuring lesions was also considered for analysis. Each lesion was imaged in vivo by a multispectral imaging system. The system operates at wavelengths between 483 and 950 nm by acquiring 15 images at equally spaced wavelength intervals. From the images, different lesion descriptors were extracted related to the colour distribution and morphology of the lesions. Data reduction techniques were applied before setting up a neural network classifier designed to perform automated diagnosis. The data set was randomly divided into three sets: train (696 lesions, including 90 melanomas) and verify (348 lesions, including 53 melanomas) for the instruction of a proper neural network, and an independent test set (347 lesions, including 41 melanomas). The neural network was able to discriminate between melanomas and non-melanoma lesions with a sensitivity of 80.4% and a specificity of 75.6% in the 1391 histologized cases data set. No major variations were found in classification scores when train, verify and test subsets were separately evaluated. Following receiver operating characteristic (ROC) analysis, the resulting area under the curve was 0.85. No significant differences were found among areas under train, verify and test set curves, supporting the good network ability to generalize for new cases. In addition, specificity and area under ROC curve increased up to 90% and 0.90, respectively, when the additional set of 1022 lesions without histology was added to the test set. Our data

show that performance of an automated system is greatly population dependent, suggesting caution in the comparison with results reported in the literature. In our opinion, scientific reports should provide, at least, the median values of thickness and dimension of melanomas, as well as the number of small (6 mm) melanomas.

Tomita Y, Tomida S, Hasegawa Y *et al.* Artificial neural network approach for selection of susceptible single nucleotide polymorphisms and construction of prediction model on childhood allergic asthma. *BMC Bioinformatics* 2004; 5:120. Abstract: BACKGROUND: Screening of various gene markers such as single nucleotide polymorphism (SNP) and correlation between these markers and development of multifactorial disease have previously been studied. Here, we propose a susceptible marker-selectable artificial neural network (ANN) for predicting development of allergic disease. RESULTS: To predict development of childhood allergic asthma (CAA) and select susceptible SNPs, we used an ANN with a parameter decreasing method (PDM) to analyze 25 SNPs of 17 genes in 344 Japanese people, and select 10 susceptible SNPs of CAA. The accuracy of the ANN model with 10 SNPs was 97.7% for learning data and 74.4% for evaluation data. Important combinations were determined by effective combination value (ECV) defined in the present paper. Effective 2-SNP or 3-SNP combinations were found to be concentrated among the 10 selected SNPs. CONCLUSION: ANN can reliably select SNP combinations that are associated with CAA. Thus, the ANN can be used to characterize development of complex diseases caused by multiple factors. This is the first report of automatic selection of SNPs related to development of multifactorial disease from SNP data of more than 300 patients.

Tomlin P, Clarke M, Robinson G, Roach J. Rehabilitation in severe head injury in children: outcome and provision of care. *Dev Med Child Neurol* 2002; 44(12):828-37. Abstract: Functional outcome and provision of care to 82 children (males:females 2.7:1; age range 0 to 16 years) with severe head injury were investigated. The children were admitted to the intensive care units of the Regional Neuroscience Units of the Greater Manchester and Lancashire districts of the North West Region of the UK between 1994 and 1996. A questionnaire was devised based on 12 areas of recovery and data were collected at discharge and 6 weeks, 6 months and 12 months from discharge. Data were collected during home visits and at joint assessment at 12 months with the district consultant community paediatrician (CCP). Early involvement of the CCP enhanced the provision of needs at discharge and 6 weeks after discharge, as did a period of stay in

district-level care before discharge home. CCPs received formal notification of the injured child in only 32% of cases by discharge, and 54% of cases by 6 months. Sixty-five per cent of children required early educational support but structured help reached only 55% of these children by the end of the study. Integrated planning between health and education was achieved in about half of the study population. Good physical recovery was achieved by the majority of children but parents said they did not feel prepared for the degree of help which their child still required 12 months after discharge. Children who required anticonvulsants at 12 months' follow-up scored significantly lower on cognitive potential. Psychosocial family functioning deteriorated in a substantial number of families according to parental perception. Prevalence of this perception did not diminish over the study period. Aspects of caregivers' understanding and the child's language deficits, self-care skills, fine and gross motor performance, as well as family, social, and financial consequences were assessed. A dedicated and integrated approach to assessment and provision of care across the domains of hospital, education, and community is discussed.

Tong Y, Frize M, Walker R. Extending ventilation duration estimations approach from adult to neonatal intensive care patients using artificial neural networks. *IEEE Trans Inf Technol Biomed* 2002; 6(2):188-91. Abstract: In earlier work, the research group successfully used artificial neural networks (ANNs) to estimate ventilation duration for adult intensive care unit (ICU) patients. The ANNs performed well in terms of correct classification rate (CCR) and average squared error (ASE) classifying the outcome into two classes: whether patients were ventilated for less than/equal to or for more than 8 h (< or >). The objective of new work was to apply this adult model to the estimation of ventilation with neonatal ICU (NICU) patient records. The performance obtained with the neonatal patients was comparable to that previously found with the adult database, again as measured in terms of a maximum CCR and a minimum ASE. The effectiveness of using the weight-elimination technique in controlling overfitting was again validated for the neonatal patients as it had been for our adult patients. It was concluded that the approach developed for ICU adult patients was also successfully applied to a different medical environment: neonatal ICU patients.

Topley J, Thomas A, Hobbs C, Wynne J. Detection of child sexual abuse. *Am J Obstet Gynecol* 2001; 184(5):1043-5.

Topp R, Cyrus J, Gebefugi I *et al*. Indoor and outdoor air concentrations of BTEX and NO<sub>2</sub>: correlation of repeated measurements. *J Environ Monit* 2004; 6(10):807-12.

Notes: CORPORATE NAME: INGA Study Group

Abstract: Studies on health effects of air pollutants ideally define exposure through the collection of air samples in the participants' homes. Concentrations derived from these samples are then considered as an estimate for the average concentration of air pollutants in the homes. Conclusions drawn from such studies therefore depend very much on the validity of the measured air pollution concentrations. In this paper we analysed repeated BTEX and NO<sub>2</sub> measurements with a time period of several months lying between the two conducted home visits. We investigated the variability of their concentrations over time by determining correlation coefficients and calculating within- and between-home variances. Our population consisted of 631 homes of participants from two cohort studies within the framework of the German study on Indoor Factors and Genetics in Asthma. Air pollutants were measured using passive samplers both indoors and outdoors. The measured BTEX concentrations were poorly correlated, with Pearson's correlation coefficient *r* ranging from -0.19 to 0.27. Additionally, a considerable seasonal effect could be observed. A higher correlation was found for the NO<sub>2</sub> concentrations with *r* ranging between 0.24 and 0.55. For the BTEX, the between-home variance was bigger than the within-home variance, for NO<sub>2</sub> both variances were of about the same order. Our results indicate that in a setting of moderate climate like in Germany, the variability of BTEX and NO<sub>2</sub> concentrations over time is high and a single measurement is a poor surrogate for the long-term concentrations of these air pollutants.

Tornqvist K, Kallen B. Risk factors in term children for visual impairment without a known prenatal or postnatal cause. *Paediatr Perinat Epidemiol* 2004; 18(6):425-30.

Abstract: Risk factors were studied for visual impairment in children without known pre- or postnatal cause, for a decrease of visual acuity. Children born at term 1979-98 and with a visual impairment were identified from the Swedish Register of Visually Impaired Children and data were linked with the Swedish Medical Birth Registry. Maternal characteristics such as maternal age, parity, maternal smoking habits in early pregnancy, maternal education, nationality, and subfertility were studied as well as maternal diagnoses such as pre-eclampsia, prolonged second stage of labour, abruptio placentae, and placenta praevia. Mode of delivery was analysed as well as birthweight, and birthweight in relation to gestational age. Abruptio placentae turned out to be the strongest risk factor (OR = 8.24 [95% CI 5.01, 13.51]). Smoking did not give a statistically significant increased risk. There is an increased risk with breech delivery (OR = 2.01 [95% CI 1.28, 3.17]). Pre-eclampsia was associated with an increased risk (OR = 2.22 [95% CI 1.46, 3.38]). There is also an increase in risk at low birthweight and small-for-gestational-age as well as birthweight > 4 kg and large-for-gestational-

age. In this study we found that risk factors particularly worth noticing in term children with a presumed perinatal cause of visual impairment are abruptio placentae, pre-eclampsia, excessively low as well as excessively high birthweight, and breech delivery, a fact worth noticing in current discussion on risks, advantages or excessive exploitation of caesarean section.

Torres C, Mujica OJ. [Health, equity, and the Millennium Development Goals]. *Rev Panam Salud Publica* 2004; 15(6):430-9.

Abstract: In September 2000 representatives of 189 countries met for the Millennium Summit, which the United Nations convened in New York City, and adopted the declaration that provided the basis for formulating the Millennium Development Goals (MDGs). The eight goals are part of a long series of initiatives that governments, the United Nations system, and international financial institutions have undertaken to reduce world poverty. Three of the eight goals deal with health, so the health sector will be responsible for implementing, monitoring, and evaluating measures proposed to meet targets that have been formulated: to reduce by two-thirds the mortality rate in children under 5 years of age between 1990 and 2015; to reduce by three-quarters the maternal mortality rate between 1990 and 2015; and to halt and begin to reverse the spread of HIV/AIDS by the year 2015, as well as to halt and begin to reverse the incidence of malaria, tuberculosis, and other major diseases. The health sector must also work with other parties to achieve targets connected with two other of the goals: to improve access to affordable essential drugs, and to reduce the proportion of persons who do not have safe drinking water. Adopting a strategy focused on the most vulnerable groups—ones concentrated in locations and populations with the greatest social exclusion—would make possible the largest total reduction in deaths among children, thus reaching the proposed target as well as producing greater equity. In the Region of the Americas the principal challenges in meeting the MDGs are: improving and harmonizing health information systems; designing health programs related to the MDGs that bring together the set of services and interventions that have the greatest impact, according to the special characteristics of the populations who are intended to be the beneficiaries; strengthening the political will to support the MDGs; and guaranteeing funding for the measures undertaken to attain the MDGs.

Torrey EF. Early physical and sexual abuse associated with an adverse course of bipolar illness. *Biol Psychiatry* 2002; 52(8):843; author reply 843-5.

Torrey WC, Lynde DW, Gorman P. Promoting the implementation of practices that are supported by

research: the National Implementing Evidence-Based Practice Project. *Child Adolesc Psychiatr Clin N Am* 2005; 14(2):297-306, ix.

Abstract: The National Implementing Evidence-Based Practice Project is an ongoing effort to promote the implementation of effective practices for adults who have severe mental illnesses. The project members designed and developed integrated packages of materials and services to help practice sites implement evidence-based practices and is field-testing the approach in eight states. These implementations are being evaluated carefully to learn how to make the technology transfer process more efficient in the future. This article describes the project and provides some early reflections on the implementation experience.

Totet A, Latouche S, Lacube P *et al.* *Pneumocystis jirovecii* dihydropteroate synthase genotypes in immunocompetent infants and immunosuppressed adults, Amiens, France. *Emerg Infect Dis* 2004; 10(4):667-73.

Abstract: To date, investigations of *Pneumocystis jirovecii* circulation in the human reservoir through the dihydropteroate synthase (DHPS) locus analysis have only been conducted by examining *P. jirovecii* isolates from immunosuppressed patients with *Pneumocystis pneumonia* (PCP). Our study identifies *P. jirovecii* genotypes at this locus in 33 immunocompetent infants colonized with *P. jirovecii* contemporaneously with a bronchiolitis episode and in 13 adults with PCP; both groups of patients were monitored in Amiens, France. The results have pointed out identical features of *P. jirovecii* DHPS genotypes in the two groups, suggesting that in these groups, transmission cycles of *P. jirovecii* infections are linked. If these two groups represent sentinel populations for *P. jirovecii* infections, our results suggest that all persons parasitized by *P. jirovecii*, whatever their risk factor for infection and the form of parasitism they have, act as interwoven circulation networks of *P. jirovecii*.

Towner E, Dowswell T. Community-based childhood injury prevention interventions: what works? *Health Promot Int* 2002; 17(3):273-84.

Abstract: Unintentional injury, with its broad range of injury types, possible countermeasures, and great number of agencies involved in its prevention, lends itself to community-based approaches. In this paper we examine 10 community-based injury prevention programmes that have targeted childhood injury prevention and have been evaluated using some measure of outcome. We investigate the nature of the intervention, targeting, the length of programmes and multi-agency involvement. We also consider how the programmes have been evaluated, and what outcome, impact and process measures have been used. The information on the intervention and how it was evaluated, how effective the programme was, and the strength of the evidence, is summarized in tabular form. There is increasing evidence emerging about the

effectiveness of community-based approaches in injury prevention. Important elements of such approaches are long-term strategy, effective focused leadership, multi-agency collaboration, tailoring to the needs of the local community, the use of local injury surveillance, and time to coordinate existing and develop new local networks. We recommend that there is a need to develop indicators to assess and monitor a culture of safety, programme sustainability and long-term community involvement.

Traeen B, Spitznogle K, Beverfjord A. Attitudes and use of pornography in the Norwegian population 2002. *J Sex Res* 2004; 41(2):193-200.

Abstract: The purpose of this study was to describe and analyze use of pornographic material in a representative sample of adult Norwegians. The data collection was carried out by means of a standardized questionnaire administered via personal telephone interviews. Among the 90% of participants who reported ever having examined pornography, 76% reported examining a pornographic magazine, 67% had watched a pornographic film, and 24% had examined pornography on the Internet. Significant gender differences emerged in the reporting. The percentage of men and women who reported frequent use of pornography was small. We identified three dimensions of attitudes toward pornography: pornography as a means of sexual enhancement, pornography as a moral issue, and social climate. These attitude dimensions were included in path models as mediating variables between demographic variables (age, gender, and level of education) and frequency of reading or watching pornographic materials. These models explained 36% of the variance in frequency of watching pornographic films, 35% of the variance in frequency of reading pornographic magazines, and 21% of the variance in frequency of watching pornography on the Internet.

Tripp MK, Carvajal SC, McCormick LK *et al.* Validity and reliability of the parental sun protection scales. *Health Educ Res* 2003; 18(1):58-73.

Abstract: Skin cancer is the most common cancer diagnosed in the US and its incidence continues to rise. Epidemiological studies have shown that excessive sun exposure received during childhood may increase the risk of developing skin cancer later in life. Yet, there are few published reports on the development of reliable and valid theory-based scales that assess the factors associated with parental sun-protection practices to reduce sun exposure in preschool children. To fill this gap, the Parental Sun Protection Scales were developed and validated. Two series of confirmatory factor analytic models were employed to

test the factor structure of the scales and to examine the inter-relationships among the proposed psychosocial factors. Sunscreen-use and sun-avoidance behavioral models were tested in a sample of 384 parents. The results provided a basis for the reliable and valid measurement of psychosocial factors related to parental sun-protection practices. These scales may be useful in more fully understanding the determinants of sun-protection behaviors and in evaluating intervention programs designed to improve such behaviors.

Tritten J. How do you feel about giving up your freedom? *Midwifery Today Int Midwife* 2002; (61):47.

Trostle LC. Overrating pornography as a source of sex information for university students: additional consistent findings. *Psychol Rep* 2003; 92(1):143-50. Abstract: This study is an empirical investigation of how 175 university students obtained their knowledge of sexual matters and whether pornography functioned as an important source. Analysis indicated that pornography does not play an important role in the dissemination of sexual information; peers appear to be the primary source. There are, however, certain statistically significant differences between the sexes in reports of the extent of specific sexual information from pornography on matters such as oral and anal intercourse. The findings extend research on pornography as a source of sex information and are contrasted with previous studies.

Troxel WM, Matthews KA. What are the costs of marital conflict and dissolution to children's physical health? *Clin Child Fam Psychol Rev* 2004; 7(1):29-57.

Abstract: Do parental marital conflict and dissolution influence the risk trajectory of children's physical health risk? This paper reviews evidence addressing this question in the context of understanding how early environmental adversities may trigger a succession of risks that lead to poor health in childhood and greater risk for chronic health problems in adulthood. We first review existing evidence linking marital conflict and dissolution to offspring's physical health outcomes. Next, we provide evidence supporting biopsychosocial pathways that may link marital conflict and dissolution with accelerated health risk trajectories across the lifespan. Specifically, we posit that consequential to the stresses associated with marital conflict and disruption, parenting practices are compromised, leading to offspring deficits in affective, behavioral, and cognitive domains. These deficits, in turn, are hypothesized to increase health risk through poor health behaviors and by altering physiological stress-response systems, including neuroendocrine, cardiovascular, and neurotransmitter functioning. On the basis of the available direct evidence and theoretically plausible pathways, it appears that there is a cost of marital conflict and disruption to children's health; however, more comprehensive investigations are needed to

further elucidate this relationship. In the final section, we address limitations in the current literature and identify research that is needed to better evaluate the association between marital conflict and dissolution and children's physical health.

Tsao JC, Glover DA, Bursch B, Ifekwunigwe M, Zeltzer LK. Laboratory pain reactivity and gender: relationship to school nurse visits and school absences. *J Dev Behav Pediatr* 2002; 23(4):217-24.

Abstract: Currently, there are no clear methods for identifying children vulnerable to frequent school absences. Our study examined relationships between gender and laboratory pain reactivity to the cold-pressor task (CPT), and parent-involved school absences and self-initiated school nurse visits in 57 children (36 female; ages 8-10 years). Using multiple regression analyses, CPT pain ratings, tolerance, and gender were analyzed in relation to nurse visits and absences collected prospectively across 2 years. We found that higher pain ratings and female gender predicted more absences; female gender also predicted increased nurse visits for acute complaints with documented physical findings. Our results suggest that laboratory pain reactivity is a potentially useful indicator of vulnerability to parent-involved functional impairment, as indexed by school absences, and that girls are more likely than boys to miss school and visit the nurse for acute illnesses. Limitations and pathways for further study are discussed.

Tulananda O, Roopnarine JL. Mothers' and fathers' interactions with preschoolers in the home in northern Thailand: relationships to teachers' assessments of children's social skills. *J Fam Psychol* 2001; 15(4):676-87.

Abstract: Using ecocultural theory as a guide, the authors observed some everyday activities of mothers and fathers with children for 2 hr in the home in 53 families residing in Chaing Mai Province in northern Thailand. Teachers provided assessments of children's general social skills in preschool using the Preschool Kindergarten Behavior Scale (K. W. Merrell, 1994). Mothers were significantly more likely to engage in basic care, general conversations, and educational activities; to praise; and to use commands and reasoning as forms of discipline with children than fathers. Mothers and fathers did not significantly differ in the display of affection, teasing or joking, and modes of play interactions with children. Parents generally treated boys and girls similarly. Few associations between parent-child involvement and children's social skills in preschool were significant. Data are discussed with respect to changes in culturally driven parent-child practices.

Tung WL, Quek C. GenSo-FDSS: a neural-fuzzy decision support system for pediatric ALL cancer subtype identification using gene expression data. *Artif Intell*

*Med* 2005; 33(1):61-88.

Abstract: OBJECTIVE: Acute lymphoblastic leukemia (ALL) is the most common malignancy of childhood, representing nearly one third of all pediatric cancers. Currently, the treatment of pediatric ALL is centered on tailoring the intensity of the therapy applied to a patient's risk of relapse, which is linked to the type of leukemia the patient has. Hence, accurate and correct diagnosis of the various leukemia subtypes becomes an important first step in the treatment process. Recently, gene expression profiling using DNA microarrays has been shown to be a viable and accurate diagnostic tool to identify the known prognostically important ALL subtypes. Thus, there is currently a huge interest in developing autonomous classification systems for cancer diagnosis using gene expression data. This is to achieve an unbiased analysis of the data and also partly to handle the large amount of genetic information extracted from the DNA microarrays. METHODOLOGY: Generally, existing medical decision support systems (DSS) for cancer classification and diagnosis are based on traditional statistical methods such as Bayesian decision theory and machine learning models such as neural networks (NN) and support vector machine (SVM). Though high accuracies have been reported for these systems, they fall short on certain critical areas. These included (a) being able to present the extracted knowledge and explain the computed solutions to the users; (b) having a logical deduction process that is similar and intuitive to the human reasoning process; and (c) flexible enough to incorporate new knowledge without running the risk of eroding old but valid information. On the other hand, a neural fuzzy system, which is synthesized to emulate the human ability to learn and reason in the presence of imprecise and incomplete information, has the ability to overcome the above-mentioned shortcomings. However, existing neural fuzzy systems have their own limitations when used in the design and implementation of DSS. Hence, this paper proposed the use of a novel neural fuzzy system: the generic self-organising fuzzy neural network (GenSoFNN) with truth-value restriction (TVR) fuzzy inference, as a fuzzy DSS (denoted as GenSo-FDSS) for the classification of ALL subtypes using gene expression data. RESULTS AND CONCLUSION: The performance of the GenSo-FDSS system is encouraging when benchmarked against those of NN, SVM and the K-nearest neighbor (K-NN) classifier. On average, a classification rate of above 90% has been achieved using the GenSo-FDSS system.

Turgay A. Aggression and disruptive behavior disorders in children and adolescents. *Expert Rev Neurother* 2004; 4(4):623-32.

Abstract: Aggression is a common symptom of many psychiatric disorders including attention deficit hyperactivity disorder, oppositional defiant disorder, conduct disorder, Tourette's disorder, mood disorders (including bipolar disorder), substance-related disorders, alcohol-related disorders, mental retardation, pervasive developmental disorders, intermittent explosive disorder and personality disorders (particularly antisocial personality disorder). Many forms of organic brain disorders may present with aggressive behavior. Aggression is common in some epileptic patients and some endocrinological diseases (e.g., diabetes and hyperthyroidism) may be associated with aggressive behavior. Physicians need to rule out many medical and psychiatric disorders before diagnosing aggressive behavior. A thorough diagnostic work up is the most important step in determining the nature of comorbid disorders associated with the behavioral problem. Structured interviews and rating scales completed by patients, parents, teachers and clinicians may aid the diagnosis and provide quantification for the change process related to treatment. The integration of medication, individual and family counseling, educational and psychosocial interventions including the school and community, may increase the effectiveness of interventions. Due to the common association of aggression and disruptive behaviors with attention deficit hyperactivity disorder, psychostimulants including new generation long-acting medications and other nonstimulant medications are considered the drug of choice for managing aggressive behavior and disruptive behavior disorders. Severe aggressive behavior not responding to these medications may require the single or combined use of mood regulators including lithium and/or antipsychotic medications. Drugs such as risperidone (Risperdal, Janssen-Cilag) have documented effectiveness and safety in children and adolescents, and can be used in treatment.

Turgay A. Treatment of comorbidity in conduct disorder with attention-deficit hyperactivity disorder (ADHD). *Essent Psychopharmacol* 2005; 6(5):277-90. Abstract: Conduct disorder (CD) is one of the most common psychiatric disorders in childhood and adolescence. It is characterized by a variety of chronic antisocial behaviors, a repetitive and persistent pattern of behavior that violates the basic rights of others, major age-appropriate societal norms, or both. Aggressive behavior, lying, stealing, fire-setting, and running away from home and school are the most frequent manifestations of CD and are often accompanied by hyperactivity, impulsive behavior,

explosiveness, cognitive and learning problems, and poor social skills. The rate of comorbidity is high, with attention-deficit hyperactivity disorder (ADHD) and oppositional defiant disorder (ODD) being the most common; comorbid anxiety and depressive disorders are also seen, especially in adolescents. The diagnostic process should include the use of structured interviews, and scores from reliable and valid rating scales that cover all psychiatric disorders must be considered in the differential diagnosis, because CD alone is an extreme rarity and multiple disorders are almost always the rule rather than exception. Treatment should include parenting skills training combined with training of the child to improve his or her relationships with peers, academic performance, and compliance with legitimate demands of authority figures. The appropriate use of medications and integration of patient/parent education and support, as well as individual, group, family, residential, and inpatient treatment may be beneficial for patients with CD and ADHD. The article describes a number of psychopharmacological agents that are used in patients with CD with ADHD and other comorbid disorders. Drugs that may be useful include psychostimulants; atomoxetine (Strattera); antidepressants (imipramine [Tofranil], desipramine [Norpramin]); Selective Serotonin Reuptake Inhibitors (SSRIs); atypical antipsychotics such as risperidone (Risperdal); or mood regulators including lithium (Eskalith).

Twemlow SW, Fonagy P, Sacco FC. A developmental approach to mentalizing communities: I. A model for social change. *Bull Menninger Clin* 2005; 69(4):265-81.

Abstract: A developmental model is proposed applying attachment theory to complex social systems to promote social change. The idea of mentalizing communities is outlined with a proposal for three projects testing the model: ways to reduce bullying and create a peaceful climate in schools, projects to promote compassion in cities by a focus of end-of-life care, and a mentalization-based intervention into parenting style of borderline and substance abusing parents.

Twetman S, Petersson L, Axelsson S *et al.* Caries-preventive effect of sodium fluoride mouthrinses: a systematic review of controlled clinical trials. *Acta Odontol Scand* 2004; 62(4):223-30.

Abstract: The Swedish Council on Technology Assessment in Health Care launched a project group in 1999 to systematically review and evaluate the existing literature on different caries-preventive methods. The aim of this article was to report the findings concerning the caries-preventive effect of fluoride mouthrinses (FMRs) in various age groups, with special reference to background fluorides. A systematic search in electronic databases for literature published between 1966 and August 2003 was conducted with the inclusion criteria of a randomized or controlled clinical trial, at least 2 years' follow-up, and caries increment in the permanent dentition (DeltaDMFS/T) as endpoint. Out of 174 articles originally identified, 62 met the inclusion criteria. These studies were assessed independently by at least two reviewers and scored A-C according to predetermined criteria for methodology and performance. The measure of effect was the prevented fraction (PF) expressed as percent. The level of evidence was based on 25 articles. The results revealed limited evidence (evidence level 3) for the caries-preventive effect (PF 29%) of daily or weekly sodium fluoride rinses compared with placebo in permanent teeth of schoolchildren and adolescents with no additional fluoride exposure and for a caries-preventive effect on root caries in older adults. Inconclusive evidence (evidence level 4) was found regarding the effect of FMRs in schoolchildren and adolescents exposed to additional fluoride sources such as daily use of fluoride toothpaste. No firm support for the use of FMRs was disclosed in a small number of studies designed for patients at caries risk. Furthermore, no association between the frequency of the rinses and prevented fraction or saved surfaces per year was found. In conclusion, this systematic review suggests that sodium fluoride mouthrinses may have an anti-caries effect in children with limited background of fluoride exposure, while its additional effect in children with daily use of fluoride toothpaste could be questioned. The need for further clinical trials to elucidate the effect of FMRs in risk patients and older adults is emphasized.

Twombly R. For gene therapy, now-quantified risks are deemed troubling. *J Natl Cancer Inst* 2003; 95(14):1032-3.

Tyagi SV. Incest and women of color: a study of experiences and disclosure. *J Child Sex Abus* 2001; 10(2):17-39. Abstract: Clinical literature on incest trauma assumes a homogeneity of experience of all incest survivors including women of color. Experiences relating to community, culture, and family need to be acknowledged as salient aspects of the experiences of women of color who are also incest survivors. Twelve participants were interviewed regarding their experiences related to disclosure and coping. Participants described value systems, community mindedness, social attitudes, negative consequences amongst other social and cultural issues as factors

affecting incest disclosure. Participants described cognitive reframing, determination and separation from the perpetrator as ways of coping with incest.

Tyden T, Rogala C. Sexual behaviour among young men in Sweden and the impact of pornography. *Int J STD AIDS* 2004; 15(9):590-3. Abstract: The purpose was to investigate the sexual behaviour among young men (n = 300), visiting a genitourinary clinic in Sweden, focusing on the impact of pornography. Almost all, 98% (n = 292) claimed to be heterosexual. The mean age at first intercourse was 16 years and on that occasion 64% (n = 187) used some kind of contraceptive, mainly condom. All, 99% (n = 296) had consumed pornography and 53% (n = 157) felt that pornography impacted their sexual behaviour; they got inspired. About half (n = 161) had had anal intercourse. Of these, 70% (n = 113) had had it more than once and 84% (n = 133) could imagine doing it again. Only 17% (n = 28) always used a condom in this situation. One out of four (n = 70) had had at least one sexually transmitted disease. The low use of condoms when heterosexual men have anal sex might have serious consequences for a spread of sexually transmitted diseases.

Ulinski T, Lhopital C, Cloppet H *et al.* Munchausen syndrome by proxy with massive proteinuria and gastrointestinal hemorrhage. *Pediatr Nephrol* 2004; 19(7):798-800.

Abstract: A 5-year-old boy presented with acute abdominal pain. Massive proteinuria of 10 g/1.73 m(2) per day was detected on standard urinalysis. There was no peripheral edema. Serum concentrations of total proteins, lipids, and creatinine and immunological investigations were normal. Two kidney biopsies revealed no abnormalities. Several weeks later he was admitted for intestinal hemorrhage with significant anemia. Endoscopy of the esophagus, stomach, colon, and small bowel (via laparotomy) were normal. Electrophoresis of urine proteins revealed the unusual finding of an albumin fraction of 99.4%. During a routine check-up in the outpatient clinic fresh urine samples were obtained while the boy's mother was absent. These were all negative for protein. The mother, who was a nurse, finally confessed to adding human albumin to the urine samples.

Ullman SE, Filipas HH. Ethnicity and child sexual abuse experiences of female college students. *J Child Sex Abus* 2005; 14(3):67-89.

Abstract: This research examines the understudied issue of race/ethnicity in relation to child sexual abuse experiences (CSA) in a cross-sectional convenience sample of 461 female college students completing a survey. Comparisons of students' abuse experiences revealed ethnic differences in sexual abuse prevalence, severity of abuse, the victim-offender relationship and post-abuse coping. Black students reported more sexual abuse than other ethnic groups, followed by Hispanics, Whites, and Asians. Although timing and extent of disclosure of sexual abuse did not vary by ethnicity, negative social reactions to disclosure were more common for certain ethnic groups than others. No ethnic differences emerged for depressive or PTSD symptoms. Implications are drawn for future research on the issue of ethnic differences in the aftermath of CSA experiences.

Umar US, Adekunle AO, Bakare RA. Pattern of condom use among commercial sex workers in Ibadan, Nigeria. *Afr J Med Med Sci* 2001; 30(4):285-90. Abstract: Regular condom use has been proven to remarkably reduce the transmission of sexually transmitted diseases (STDs) and its regular use for casual and commercial sex is important for the success of any STD/AIDS control programme. We studied the pattern of condom use among commercial sex workers in Ibadan, Nigeria in an attempt to identify the factors associated with it. Two hundred and ninety-five commercial sex workers in 21 brothels were randomly selected, using a multi-stage sampling technique, from a total of 31 identified in the 5 local government areas that make up Ibadan municipality. They were administered a pre-tested, semi-structured questionnaire by trained research assistants. Results showed that over half (53.2%) of the respondents were in the 20-29 year age group and most (71.5%) had been in the profession for less than a year. Sixty-five (22.0%) had no formal education, 29.8 % had some secondary education whilst 22.4 % had completed secondary school. Their overall knowledge of sexually transmitted diseases (STDs) was rated as poor (20.7%), moderate (64.1%) and good (15.2%). Their perceived risk of contracting HIV/AIDS was low (21.7%) although 87.8% regard it as a health problem in Nigeria. Eighty-three percent of the respondents always insisted that their clients used condoms, 13.2% did so frequently whilst 1.4% only occasionally. Of those who asked clients to use condoms, 69.5% of the women would refuse sex without condoms, 49 (16.6%) would do nothing and have sex without condoms, but 4.4% would charge extra money. No factor was found to have a significant association with the practice of asking clients to use condoms or of refusing sex without condoms. We concluded that consistent condom use was high among sex workers in brothels in Ibadan and was independent of the sex workers knowledge and perception of STDs.

Untalan F, Woodruff K, Hardy C, Liao M, Krupitsky D. Disparities in outcomes for pediatric cancer patients treated in Hawai'i: comparing Hawai'i residents to children referred from the Pacific Islands. *Pac Health Dialog* 2004; 11(2):114-9. Abstract: This article examines whether pediatric cancer patients referred to Hawai'i from the Pacific Islands had poorer outcomes than Hawai'i residents treated at the same hospital. For children admitted from 1981 to 2002, we obtained data on patient demographics and outcomes from a review of medical charts and physician case reviews. We found that pediatric cancer patients referred from the Pacific Islands for treatment in Hawai'i had a higher relative risk of death, of not receiving treatment in a timely manner, of not completing treatment, and of being lost to follow-up than pediatric cancer patients that were residents of Hawai'i. The higher risk of poor outcomes for pediatric cancer patients referred from the Pacific Islands can be addressed by improving the health care systems in both the Pacific Islands and in Hawai'i.

Upadhyay K, Thomson A, Luckas MJ. Congenital myotonic dystrophy. *Fetal Diagn Ther* 2005; 20(6):512-4. Abstract: We describe a case of severe congenital myotonic dystrophy (CDM). A 38-year-old primigravida, who was known to suffer from mild myotonic dystrophy (DM), conceived spontaneously and booked for confinement at 11 weeks in our unit. The couple had been fully counseled about the risks of transmission of this condition to their offspring before embarking on this pregnancy. Despite being fully aware of the risks, they declined prenatal diagnosis. The pregnancy was monitored by serial ultrasound scans. The diagnosis of CDM was suspected by ultrasound markers of borderline ventriculomegaly, polyhydramnios, and reduced fetal movements. The pregnancy ended prematurely at 33 weeks in an emergency caesarean section because of severe fetal compromise. The neonate died almost immediately after birth. The genetic analysis of cord blood confirmed severe DM. This case highlights the importance of ultrasound markers for the diagnosis of CDM in the absence of definitive prenatal diagnosis.

Uppard S. Child soldiers and children associated with the fighting forces. *Med Confl Surviv* 2003; 19(2):121-7. Abstract: Experience has shown that the breakdown of protective structures such as families and communities, particularly in times of conflict, leaves children vulnerable to recruitment into armed groups. These children are subject to gross violations of their human rights, such as the right to protection from harm, violence and abuse. At least 300,000 children are currently being used to fight in armed conflicts in over 30 countries across the world. Girls and boys are

abducted, coerced or persuaded to join armed forces, often in brutal circumstances. These children are usually involved in internal conflicts, where poverty and exclusion leave very few other viable options--becoming soldiers may appear to be their only means of survival. Many, however, sustain physical injuries and permanent disabilities as a result of combat and it is impossible to know how many are killed. A large number encounter health problems such as sexually transmitted diseases, including HIV/AIDS. Lack of data on the health of child soldiers means that appropriate medical care and treatment may be inadequate or inaccessible, even during a planned demobilization. There is an urgent need for systematic research and data collection in order to better understand and provide for the healthcare of all children leaving armed groups.

Uribe-Salas F, Conde-Glez CJ, Juarez-Figueroa L, Hernandez-Castellanos A. Sociodemographic dynamics and sexually transmitted infections in female sex workers at the Mexican-Guatemalan border. *Sex Transm Dis* 2003; 30(3):266-71. Abstract: BACKGROUND: If the predominant means of HIV transmission is heterosexual in the Soconusco region of Mexico, then the female sex workers (FSWs) from Central America who work in this region may be playing a significant role in the heterosexual transmission of HIV. GOAL: The goal was to estimate the prevalence of several sexually transmitted infections (STIs), including HIV infection, and to evaluate the population mobility of Mexican and Central American FSWs in the Soconusco region in Chiapas State, Mexico. METHODS: A cross-sectional study was conducted upon the construction of a sampling frame of sex work-related bars in the municipalities of the Soconusco region. Consenting participants answered a questionnaire that recorded sociodemographic characteristics, previous and current experience in commercial sex, and risk indicators for STI. Women also provided blood and endocervical swab specimens to be analyzed. RESULTS: A sample of 484 women were enrolled, who were characterized as follows: the average age was 25.6 years, and a high proportion had children, were single, had started sexual activity at an early age, and had a low level of education and low earnings. The global prevalences of infections with *Treponema pallidum*, HSV-2, HIV, *Neisseria gonorrhoeae*, and *Chlamydia trachomatis* were 9.4%, 85.7%, 0.6%, 11.6%, and 14.4%, respectively. Frequencies of HBcAb and HBsAg hepatitis B markers were 17.7% and 1.3%. The cumulative prevalence of treatable gonorrhea, chlamydia, and syphilis was 27.4%. CONCLUSION: The data on women's mobility illustrate that the Soconusco region attracts Central American women to enter the commercial sex trade. The women's sociodemographic characteristics were consistent with high prevalences of STI, except HIV infection. The low frequency of HIV infection suggests that this

population may have had little contact with HIV core groups in Central America and in the Soconusco and no history of blood transfusion or intravenous drug use.

Uscinski RH, Thibault LE, Ommaya AK. Rotational injury. *J Neurosurg* 2004; 100(3):574-5; author reply 575.

V Essen H, Schlickewei W, Dietz HG. [Child abuse]. *Unfallchirurg* 2005; 108(2):92-101. Abstract: Child abuse is most often diagnosed by an emergency doctor on call who sometimes "feels" more than knows what he is confronted with. He should nevertheless always take a medical history and make a physical and radiological examination. X-ray imaging and an ophthalmologic retinal examination are the most important diagnostic steps. Typical findings are multiple and/or dorsal rib fractures, complex skull fractures, physal fractures, all fractures within the first 12 months, multiple fractures in different localisations and stages of healing, all injuries with uncommon distributions, all patterned bruises, immersion burns, intramural hematoma and every unexplained loss of consciousness. The first step towards victim protection is always the removal of the abused child from its caregivers by admitting it to hospital, as 95% of all cases of reported child abuse take place within the child's family.

Valdizan JR, Abril-Villalba B, Mendez-Garcia M *et al.* [Cognitive evoked potentials in autistic children]. *Rev Neurol* 2003; 36(5):425-8. Abstract: AIMS: The aim of this study was to examine the latency, amplitude and distribution of N400 potential in order to evaluate the semantic processing capacity in autistic children and in children suffering from Asperger's syndrome (AS), and to compare them with a control group. PATIENTS AND METHODS: 24 autistic children, six boys with AS and 25 controls, aged between 6 and 14 years old. The cases were examined using the DSM IV diagnostic criteria. Auditory stimulation was performed with pairs of congruent and incongruent words: two lists of 20 pairs of semantically related words (congruent) and 20 pairs of words with no semantic relationship whatsoever (incongruent). RESULTS: The most striking parameter is the increase in latency in N400 for the group of autistic children, which did not occur in the group of children with AS. Maximum N400 negativity for the children with autism was found in the left frontocentral region. No significant differences were observed for the amplitude of N400 between the three groups that were studied. CONCLUSION: Neurophysiologically,

the autistic children and those affected by AS perhaps use different neuronal networks in semantic processing. The N400 wave can be a valid test for monitoring verbal processing in these children.

Valentin SR. Commentary: Sleep in German infants--the "cult" of independence. *Pediatrics* 2005; 115(1 Suppl):269-71.

Abstract: OBJECTIVES: Significant cultural variations exist in sleep practices for young children, including bedtime rituals and routines, soothing techniques, and cosleeping. This study examined parenting styles at bedtime and sleep behavior in a group of German infants. The results are compared with sleep practices of other western European countries. PARTICIPANTS: German parents of 50 boys and 50 girls 6 to 30 months old. METHOD: Parents were asked to fill out a questionnaire about the sleep behavior of their child. Personal interviews with the parents were conducted to augment the survey results; in selected cases, bedtime routines were filmed. RESULTS: The infants in this sample largely slept in their own bed in a separate room. Bedtime rituals were common and in general characterized by parents maintaining behavioral distance from the infants during the bedtime routine. However, parenting style was likely to become more "proximal" (close) in response to bedtime refusal and nocturnal infant crying. A majority of parents (79%) used lullabies as part of the bedtime ritual, and the use of a sleep aid was very common (80%). CONCLUSION: As is the case with most cultures, German bedtime parenting practices tend to reflect parenting values and beliefs associated with their specific culture. The parenting style at bedtime in this group of infants in general seemed less rigid and less distancing than bedtime rituals typically described in other northern European countries and may represent more of a synthesis of parenting styles across various Western cultures.

Van Biema D. Rebels in the pews. *Time* 2002; 159(24):54-8.

van den Bree MB, Pickworth WB. Risk factors predicting changes in marijuana involvement in teenagers. *Arch Gen Psychiatry* 2005; 62(3):311-9. Abstract: BACKGROUND: Marijuana use during adolescence has various adverse psychological and health outcomes. It is poorly understood whether the same risk factors influence different stages in the development of marijuana involvement. OBJECTIVE: To establish which risk factors best explain different stages of marijuana involvement. DESIGN: Data were collected at 2 points using computer-assisted personal interview (wave 1 and wave 2 were separated by 1 year). Twenty-one well-established risk factors of adolescent substance use/abuse were used to predict 5 stages of marijuana involvement: (1) initiation of experimental use, (2) initiation of regular use, (3) progression to regular use, (4) failure to discontinue

experimental use, and (5) failure to discontinue regular use. Data were analyzed using logistic regression analysis. PARTICIPANTS: Middle school and high school students (N = 13 718, aged 11-21 years) participating in the National Longitudinal Study of Adolescent Health (Add Health). RESULTS: Three risk factors (own and peer involvement with substances, delinquency, and school problems) were the strongest predictors of all stages. Their combined presence greatly increased risk of initiation of experimental (odds ratio, 20) and regular (odds ratio, 87) marijuana use over the next year. Personality, family, religious, and pastime factors exerted stage-specific, sex-specific, and age-specific influences. CONCLUSIONS: Assessment of substance, school, and delinquency factors is important in identifying individuals at high risk for continued involvement with marijuana. Prevention and/or intervention efforts should focus on these areas of risk.

van der AA F, Roskams T, Blyweert W, Ost D, Bogaert G, De Ridder D. Identification of kit positive cells in the human urinary tract. *J Urol* 2004; 171(6 Pt 1):2492-6. Abstract: PURPOSE: Analogous to interstitial cells of Cajal in the bowel, functional important networks of interstitial cells could have a role in the complex mechanism of central and peripheral control of urinary tract function. Recently various reports mentioned the presence of interstitial cells in different parts of the urinary tract and in different species. Since important differences among species exist, we performed immunohistochemistry on fresh frozen human tissue to study the presence of interstitial cells in the human urinary tract. MATERIALS AND METHODS: A total of 65 tissue pieces from all levels of the urinary tract were obtained from 44 patients treated at our institution. Tissue was processed for immunohistochemistry immediately after removal. We performed immunohistochemistry for kit, connexin 43 and VRL1/TRPV2. RESULTS: Interstitial cells immunopositive for all 3 antibodies were seen beneath the urothelium and between smooth muscle cells in all tissue pieces with slight topographical differences. CONCLUSIONS: Together with morphological and functional data from other experiments these morphological data suggest that, as in the bowel, networks of interstitial cells might have an important role in the physiology and pathology of the urinary tract. They could be involved in pacemaking or have an integrating role through the modulation of neurotransmission and conduction of electrical impulses. Functional experiments are the next step to study these hypotheses.

van der Heide A, Deliëns L, Faisst K *et al.* End-of-life decision-making in six European countries: descriptive study. *Lancet* 2003; 362(9381):345-50. Notes: CORPORATE NAME: EURELD consortium GENERAL NOTE: KIE: 25 refs. GENERAL NOTE: KIE: KIE Bib: allowing to die;

euthanasia; suicide; terminal care  
Abstract: BACKGROUND: Empirical data about end-of-life decision-making practices are scarce. We aimed to investigate frequency and characteristics of end-of-life decision-making practices in six European countries: Belgium, Denmark, Italy, the Netherlands, Sweden, and Switzerland. METHODS: In all participating countries, deaths reported to death registries were stratified for cause (apart from in Switzerland), and samples were drawn from every stratum. Reporting doctors received a mailed questionnaire about the medical decision-making that had preceded the death of the patient. The data-collection procedure precluded identification of any of the doctors or patients. All deaths arose between June, 2001, and February, 2002. We weighted data to correct for stratification and to make results representative for all deaths: results were presented as weighted percentages. FINDINGS: The questionnaire response rate was 75% for the Netherlands, 67% for Switzerland, 62% for Denmark, 61% for Sweden, 59% for Belgium, and 44% for Italy. Total number of deaths studied was 20480. Death happened suddenly and unexpectedly in about a third of cases in all countries. The proportion of deaths that were preceded by any end-of-life decision ranged between 23% (Italy) and 51% (Switzerland). Administration of drugs with the explicit intention of hastening death varied between countries: about 1% or less in Denmark, Italy, Sweden, and Switzerland, 1.82% in Belgium, and 3.40% in the Netherlands. Large variations were recorded in the extent to which decisions were discussed with patients, relatives, and other caregivers. INTERPRETATION: Medical end-of-life decisions frequently precede dying in all participating countries. Patients and relatives are generally involved in decision-making in countries in which the frequency of making these decisions is high.

van der Kolk BA. The neurobiology of childhood trauma and abuse. *Child Adolesc Psychiatr Clin N Am* 2003; 12(2):293-317, ix.  
Abstract: During the past decade there has been rapid progress in the understanding of the effects of exposure to traumatic life experiences on subsequent psychopathology in children. Trauma exposure affects what children anticipate and focus on and how they organize the way they appraise and process information. Trauma-induced alterations in threat perception are expressed in how they think, feel, behave, and regulate their biologic systems. The task of therapy is to help these children develop a sense of physical mastery and awareness of who they are and what has happened to them to learn to observe what is happening in present time and physically respond to current demands instead of recreating the traumatic past behaviorally, emotionally, and biologically.

van der Maesen K, Moll AC, Imhof SM. [Diagnostic image (177). A lifeless infant. Shaken baby syndrome]. *Ned Tijdschr Geneesk* 2004; 148(8):377.

Abstract: In a 4-months-old male infant who had been discovered in his bed pale, apnoeic and cold, funduscopy revealed multiple retinal haemorrhages due to shaken baby syndrome.

van der Velden VH, Hochhaus A, Cazzaniga G, Szczepanski T, Gabert J, van Dongen JJ. Detection of minimal residual disease in hematologic malignancies by real-time quantitative PCR: principles, approaches, and laboratory aspects. *Leukemia* 2003; 17(6):1013-34.  
Abstract: Detection of minimal residual disease (MRD) has prognostic value in many hematologic malignancies, including acute lymphoblastic leukemia, acute myeloid leukemia, chronic myeloid leukemia, non-Hodgkin's lymphoma, and multiple myeloma. Quantitative MRD data can be obtained with real-time quantitative PCR (RQ-PCR) analysis of immunoglobulin and T-cell receptor gene rearrangements, breakpoint fusion regions of chromosome aberrations, fusion-gene transcripts, aberrant genes, or aberrantly expressed genes, their application being dependent on the type of disease. RQ-PCR analysis can be performed with SYBR Green I, hydrolysis (TaqMan) probes, or hybridization (LightCycler) probes, as detection system in several RQ-PCR instruments. Dependent on the type of MRD-PCR target, different types of oligonucleotides can be used for specific detection, such as an allele-specific oligonucleotide (ASO) probe, an ASO forward primer, an ASO reverse primer, or germline probe and primers. To assess the quantity and quality of the RNA/DNA, one or more control genes must be included. Finally, the interpretation of RQ-PCR MRD data needs standardized criteria and reporting of MRD data needs international uniformity. Several European networks have now been established and common guidelines for data analysis and for reporting of MRD data are being developed. These networks also include standardization of technology as well as regular quality control rounds, both being essential for the introduction of RQ-PCR-based MRD detection in multicenter clinical treatment protocols.

van der Walt JH, Sainsbury DA, Pettifer R. Anaesthesia alert: an integrated, networked, register of paediatric anaesthetic problems. *Anaesth Intensive Care* 2001; 29(2):113-6.  
Abstract: The Paediatric Register of Anaesthetic Problems (PaedRAP) is a network-based anaesthesia hazard alert system. It is integrated with pre-anaesthesia consultations and patient questionnaires. All files, both electronic and on paper, are available 24 hours a day close to the operating theatres. This ensures that pertinent information is readily available when and where it is most needed. The PaedRAP is also linked to the automated theatre booking system to print warnings on the theatre lists. This minimizes the chance that important information goes unnoticed. Documentation of the progression of the various categories of patient problems and evolving

management strategies has been useful both for individuals and groups.

Van Dorn RA, Mustillo S, Elbogen EB, Dorsey S, Swanson JW, Swartz MS. The effects of early sexual abuse on adult risky sexual behaviors among persons with severe mental illness. *Child Abuse Negl* 2005; 29(11):1265-79.

Abstract: OBJECTIVE: There were two aims: first, to examine the relationship between prior sexual abuse and three types of adult risky sexual behaviors [(1) ever traded sex for drugs or money, (2) had unprotected sex in the past 6 months, and (3) frequency of unprotected sex in the past 6 months] among persons with severe mental illness (SMI), and second, to examine the potential mediating effects of adult rape, substance use, and PTSD. METHOD: Using a pooled sample of individuals with SMI (N=609), logistic and negative binomial regression analyses were used to investigate the impact of prior sexual abuse on these adult risky sexual behaviors. RESULTS: Childhood sexual abuse was associated with having ever traded sex for money and having engaged in unprotected sex in the past 6 months. However, childhood sexual abuse was inversely associated with the number of times males had unprotected sex in the past 6 months. Results differed between males and females and the impact of potential mediators also varied by gender and type of outcome studied. CONCLUSION: These findings suggest a complex link between childhood sexual abuse and adult risky sexual behaviors in persons with SMI. Clinical assessments of child abuse sequelae should include a variety of indicators and parameters of adult risky sexual behavior, as persons with SMI are at an increased risk of engaging in high-risk sexual behaviors and tend to have a higher exposure to childhood sexual abuse than does the general population.

Van Houdenhove B, Egle UT. Comment on Raphael, K.G., Widom, C.S., Lange, G., Childhood victimization and pain in adulthood: a prospective investigation, *PAIN* 92 (2001) 283-293. *Pain* 2002; 96(1-2):215-6; author reply 216-7.

van Lier PA, Crijnen AA. Trajectories of peer-nominated aggression: risk status, predictors and outcomes. *J Abnorm Child Psychol* 2005; 33(1):99-112. Abstract: Developmental trajectories of peer-nominated aggression, risk factors at baseline, and outcomes were studied. Peer nominations of aggression were obtained annually from grades 1 to 3. Three developmental trajectories were identified: an early-onset/increasers trajectory with high levels of peer-nominated aggression at elementary school entry and increasing levels throughout follow-up; a moderate-persistent trajectory of aggression in which children were characterized by moderate levels of physical aggression at baseline; and a third trajectory with stable

low levels of aggression. Children following the early-onset/increasers trajectory showed physical forms of aggression at baseline. Male gender and comorbid attention deficit/hyperactivity problems, oppositional defiant problems and poor prosocial behavior plus negative life events predicted which children would follow the early-onset/increasers trajectory of aggression. The outcomes associated with the early-onset/increaser children suggest high risk for chronically high levels of aggressive behavior.

van Loveren C, Ketley CE, Cochran JA, Duckworth RM, O'Mullane DM. Fluoride ingestion from toothpaste: fluoride recovered from the toothbrush, the expectorate and the after-brush rinses. *Community Dent Oral Epidemiol* 2004; 32 Suppl 1:54-61. Abstract: OBJECTIVES: The aim of this study was to determine the effects of rinsing and spitting on fluoride ingestion from toothpaste during normal oral-hygiene procedures of younger children, and hence to make recommendations on rinsing during toothbrushing. METHODS: The brushing habits of 166 Dutch and 185 Irish children between 1.5 and 3.5 years were observed during home visits. The weight of the toothpaste tube was determined before and after use. After brushing, the toothbrush and any associated expectorate and rinses, combined with any toothpaste spilled during the brushing procedures, were collected. The amounts of fluoride retained on the toothbrush and in the associated expectorate and rinses were measured. RESULTS: Over 90% of the Dutch children used a special toddlers' toothpaste with < or =500 ppm F. Eleven per cent of the younger (<2.5 years) Dutch children and 22% of the older children rinsed after brushing. Of the Irish children approximately 52% used a children's toothpaste containing around 500 ppm F. Of the younger Irish children 31% spat without rinsing, while another 31% rinsed during or after brushing. For the older Irish children, these percentages were 14 and 70%, respectively. On average, 22% of the fluoride dispensed on the toothbrush was retained on the brush after brushing irrespective of the rinsing and spitting behaviour of the children. The maximum ingestible amount of fluoride from toothpaste assuming no rinsing or spitting was calculated. CONCLUSIONS: Fluoride ingestion from toothpaste is significantly reduced by rinsing and/or spitting during toothbrushing. Recommendations that younger children use small amounts of toothpaste (< 0.5 g) and that children using toothpaste with > or = 1000 ppm F rinse their mouths after brushing continue to be valid.

van Manen TG, Prins PJ, Emmelkamp PM. Reducing aggressive behavior in boys with a social cognitive group treatment: results of a randomized, controlled trial. *J Am Acad Child Adolesc Psychiatry* 2004; 43(12):1478-87.

Abstract: OBJECTIVE: To evaluate the effectiveness of a social cognitive intervention program for Dutch aggressive boys and to compare it with a social skills

training and a waitlist control group. **METHOD:** A randomized, controlled treatment outcome study with 97 aggressive boys (aged 9-13 years) was presented. An 11-session group treatment, a social cognitive intervention program (n = 42) based on Dodge's social information-processing theory, was compared with social skills training (n = 40) and waitlist control group (n = 15). Measures of aggressive behavior, self-control, social cognitive skills, and appropriate social behavior were completed before and after the group treatment and at 1-year follow-up. **RESULTS:** The outcome of both treatment conditions indicated (1) a significant increase in appropriate social behavior, social cognitive skills, and self-control and (2) a significant decrease in aggressive behavior. There was a significant difference between treatment and no treatment and between the social cognitive intervention program and social skills training on various child, parent, and teacher measures. **CONCLUSIONS:** The expectation that focusing on the deficits and distortions in social cognitive processes (social cognitive intervention program) instead of merely focusing on social skills (social skills training) would enhance the effectiveness was supported on child, parent, and teacher measures. At 1-year follow-up, the mean effect sizes of the social cognitive intervention program and social skills training were 0.76 and 0.56, respectively.

Van Orden KF, Limbert W, Makeig S, Jung TP. Eye activity correlates of workload during a visuospatial memory task. *Hum Factors* 2001; 43(1):111-21. Abstract: Changes in six measures of eye activity were assessed as a function of task workload in a target identification memory task. Eleven participants completed four 2-hr blocks of a mock anti-air-warfare task, in which they were required to examine and remember target classifications (friend/enemy) for subsequent prosecution (fire upon/allow to pass), while targets moved steadily toward two centrally located ship icons. Target density served as the task workload variable; between one and nine targets were simultaneously present on the display. For each participant, moving estimates of blink frequency and duration, fixation frequency and dwell time, saccadic extent, and mean pupil diameter, integrated over periods of 10 to 20 s, demonstrated systematic changes as a function of target density. Nonlinear regression analyses found blink frequency, fixation frequency, and pupil diameter to be the most predictive variables relating eye activity to target density. Participant-specific artificial neural network models, developed through training on two or three sessions and subsequently tested on a different session from the same participant, correlated well with actual target density levels (mean R = 0.66). Results indicate that moving mean estimation and artificial neural network techniques enable information from multiple eye measures to be combined to produce reliable near-real-time indicators of workload in some visuospatial tasks. Potential applications include the monitoring of visual

activity of system operators for indications of visual workload and scanning efficiency.

Van Reempts PJ, Van Acker KJ. Ethical aspects of cardiopulmonary resuscitation in premature neonates: where do we stand? *Resuscitation* 2001; 51(3):225-32. Notes: GENERAL NOTE: KIE: KIE Bib: allowing to die/infants; patient care/minors Abstract: Advances in diagnosis, techniques, therapeutic interventions, organisation of perinatal care, and socio-economic factors have all contributed to the survival after resuscitation and intensive care of neonates with extremely low birth weight and gestational age. While morbidity during the first years of life in those infants does not increase, at school age multiple dysfunctions may become apparent. What are the limits of intensive care for the newborn? Is it right to use extreme technical and economic measures for neonates with a borderline chance of survival? What is justifiable for the neonate, the family, the society and how does legislation interfere in a decision process which involves starting, stopping or continuing intensive care? A short historical overview for the care of the newborn is given, followed by the outcome after resuscitation and treatment of the very low birth weight infant. Published management strategies and recommendations are discussed.

van Rossum AM, Oudesluis-Murphy AM. [Diagnostic image (177). A lifeless infant. Shaken baby syndrome]. *Ned Tijdschr Geneeskd* 2004; 148(23):1169; author reply 1169.

van Uden CJ, Zwietering PJ, Hobma SO *et al.* Follow-up care by patient's own general practitioner after contact with out-of-hours care. A descriptive study. *BMC Fam Pract* 2005; 6(1):23. Abstract: BACKGROUND: Little is known about the care process after patients have contacted a GP cooperative for out-of-hours care. The objective of this study was to determine the proportion of patients who seek follow-up care after contact with a GP cooperative for out-of-hours care, and to gain insight into factors that are related to this follow-up care. METHODS: A total of 2805 patients who contacted a GP cooperative for out-of-hours care were sent a questionnaire. They were asked whether they had attended their own GP within a week after their contact with the cooperative, and for what reason. To investigate whether other variables are related to follow-up care, a logistic regression analysis was applied. Variables that entered in this analysis were patient characteristics (age, gender, etc.) and patient opinion on correctness of diagnosis, urgency and severity of the medical complaint. RESULTS: The response rate was 42%. In total, 48% of the patients received follow-up care from their own GP. Only 20% were referred or advised to attend their own GP. Others attended because their medical condition worsened or because they were

concerned about their complaint. Variables that predicted follow-up care were the patient's opinion on the correctness of the diagnosis, patient's health insurance, and severity of the medical problem. CONCLUSION: Almost half of all patients in this study who contacted the GP cooperative for out-of-hours care attended their own GP during office hours within a week, for the same medical complaint. The most important factor that predicted follow-up care from the patient's own GP after an out-of-hours contact was the patient's degree of confidence in the diagnosis established at the GP cooperative. Despite the limited generalisability, this study is a first step in providing insight into the dimension of follow-up care after a patient has contacted the GP cooperative for out-of-hours primary care.

Van Zyl L. Intentional parenthood: responsibilities in surrogate motherhood. *Health Care Anal* 2002; 10(2):165-75.

Notes: GENERAL NOTE: KIE: 9 refs. GENERAL NOTE: KIE: KIE Bib: surrogate mothers Abstract: In recent years, a number of writers dealing with questions over parenthood that arise in the context of reproductive technologies and surrogate motherhood, have appealed to the notion of "intentional parenthood". Basing their argument on liberal values such as individual autonomy, the freedom to enter contracts, the right to privacy, and individual self-fulfilment, they argue that contractually stated intentions, rather than genetic or gestational relationships, should form the basis of parental rights. Against this I argue that parental rights do not derive from contractual agreements, but are based in their obligations towards the child. I then examine the nature of the obligations that the various parties have towards the child both pre- and postnatally.

Vander Stichele RH, Gyssels L, Bracke C *et al.* Wet combing for head lice: feasibility in mass screening, treatment preference and outcome. *J R Soc Med* 2002; 95(7):348-52.

Abstract: There is no scientific consensus on the best way to control head louse infestation in schoolchildren. A study was conducted to test the feasibility and acceptability of a screening campaign by wet combing and a community approach to head-lice control with home visits, and to explore parents' treatment preferences and treatment outcomes. A non-controlled intervention (advice on treatment options offered to all positive children) was nested within an epidemiological prevalence study. All children in three primary schools in Ghent, Belgium, were invited to take part in screening by wet combing (n=677, 3-11 years). Positive children were offered structural treatment advice, a home visit on day 7, and a check by wet combing on day 14. 83% of the children were screened. The prevalence of active infestation (living moving lice) was 13.0% in school 1 and 19.5% in school 3. In school 2, prevalence of signs of active and

past infestation was 40.7%. A home visit was made to 58% of the positive children. 85% of the positive children were screened again on day 14. Wet combing was the most widely used treatment, followed by chemical treatment and a combination of the two. In school 1 and 3 51% were cured, and in school 2 24% became nit-free. A wet combing screening campaign and a community-oriented approach to head-lice control is feasible though resource-intensive. The prevalence of head lice was high and the cure rate was low, with either topical treatments or wet combing.

Vandermeeren Y, Sebire G, Grandin CB, Thonnard JL, Schlogel X, De Volder AG. Functional reorganization of brain in children affected with congenital hemiplegia: fMRI study. *Neuroimage* 2003; 20(1):289-301.

Abstract: Using functional magnetic resonance imaging, the brain activation related to unilateral sequential finger-to-thumb opposition was studied in six children with a right congenital hemiplegia of cortical origin. They were compared to six age-matched controls. In the control group, movements with either hand asymmetrically activated the sensorimotor cortex and premotor areas in both cerebral hemispheres with a typical contralateral predominance. By contrast, paretic finger movements activated both hemispheres in the hemiplegic patients, with a strong ipsilateral predominance favoring the undamaged hemisphere. The activation induced by nonparetic finger movements was restricted to the contralateral undamaged hemisphere. Furthermore, the level of activation in the undamaged cortex was partly related to residual finger dexterity, according to covariance analysis. These activation patterns indicate an adaptive reorganization of the cortical motor networks in this group of patients, with a prominent involvement of the undamaged hemisphere in the control of finger movements with either hand.

VanderVoort DJ. Hawaii's public mental health system. *Hawaii Med J* 2005; 64(3):62-4, 66-7, 81.

Abstract: The following article addresses the nature of and problems with the public mental health system in Hawaii. It includes a brief history of Hawaii's public mental health system, a description and analysis of this system, economic factors affecting mental health, as well as a needs assessment of the elderly, individuals with severe mental illness, children and adolescents, and ethnically diverse individuals. In addition to having the potential to increase suicide rates and unnecessarily prolong personal suffering, problems in the public mental health system such as inadequate services contribute to an increase in social problems including, but not limited to, an increase in crime rates (e.g., domestic violence, child abuse), divorce rates, school failure, and behavioral problems in children. The population in need of mental health services in Hawaii is under served, with this inadequacy of services due to economic limitations and a variety of

other factors.

Vane DW, Sartorelli KH, Reese J. Emotional considerations and attending involvement ameliorates organ donation in brain dead pediatric trauma victims. *J Trauma* 2001; 51(2):329-31.

Abstract: **PURPOSE:** The purpose of this study was to ascertain a strategy for maximizing parental consent for organ donation in traumatically injured children suffering from brain death. Our hypothesis was that appropriate attending surgeon involvement and delay in evaluating children for brain death leads to an increased percentage of organ donors. **METHODS:** From January 1993 to August 1999, the records of all children who died in a Level I trauma center were evaluated. Those children suffering brain death that were suitable for organ donation were entered into the study. Cases were reviewed for patient demographics, time to entry into brain death protocol (measured from time of admission), time to parent notification about brain death (measured from time of admission), specific attending involved in the case (with level of involvement), and success of organ donation request. In all, 43 charts were reviewed. **RESULTS:** Of 43 deaths, 33 were deemed suitable for donation. Age of suitable donors ranged from 1 month to 18 years. In all, 11 attending physicians were involved in the care of these children. Overall, 20 of 33 were organ donors (60%). When the attending surgeon was involved, donation success for organ retrieval was 86%, whereas if the attending was not involved personally, the success rate dropped to 23% ( $p < 0.04$ ). One senior pediatric surgeon obtained a success rate of 12 of 12 children. It was this surgeon's policy to not initiate brain death protocols in children immediately on entry into the emergency room, but rather to delay initiation until family could be gathered and spend time with the affected child in order that the family could recover from the initial shock of trauma (always at least overnight). When time to initiation of brain death protocol was examined, success was obtained when a delay of 15.5 hours was respected, versus 7.0 hours when donation was requested but denied ( $p < 0.03$ ). **CONCLUSION:** These data indicate that attending involvement is important when parents of brain dead children are asked about organ retrieval ( $p < 0.04$ ). Delay in initiating brain death protocols in order for family members to deal with the shock of the initial trauma appears to increase willingness to participate in organ donation.

Varela RE, Vernberg EM, Sanchez-Sosa JJ, Riveros A, Mitchell M, Mashunkashey J. Parenting style of Mexican, Mexican American, and Caucasian-non-Hispanic families: social context and cultural influences. *J Fam Psychol* 2004; 18(4):651-7. Abstract: To begin accounting for cultural and contextual factors related to child rearing in Mexican-descent (MD; Mexican American and Mexican immigrant) families in the United States, the current

study examined parenting practices in 2-parent families of Mexican, MD, and Caucasian-non-Hispanic (CNH) parents. Parents in all groups reported using authoritative practices more often than authoritarian strategies. MD parents reported greater use of authoritarian practices than Mexican and CNH parents. Results suggest that previously found cultural variations in parenting between MD parents and CNH parents may be more related to the ecological context of MD families than to an affiliation with Mexican culture. Clinicians should explore the positive qualities of authoritative parenting in MD families along with the potential motivations for using authoritarian strategies.

Varns JL, Mulik JD, Sather ME, Glen G, Smith L, Stallings C. Passive ozone network of Dallas: a modeling opportunity with community involvement. 1. *Environ Sci Technol* 2001; 35(5):845-55. Abstract: Despite tremendous efforts toward regulating and controlling tropospheric ozone (O<sub>3</sub>) formation, a large portion of the U.S. population presently lives in environments where air quality exceeds both 1- and 8-h National Ambient Air Quality Standards (NAAQS) set for O<sub>3</sub>. High O<sub>3</sub> concentrations annually cost the United States billions of dollars in excessive human health costs, reduced crop yields, and ecological damage. This paper describes a regional networking of O<sub>3</sub> monitoring sites, operated by the public, that used simplified passive sampling devices (PSDs). In collaboration with EPA Region 6, a lay network (i.e., Passive Ozone Network of Dallas, acronym POND), consisting of 30 PSD sites in the Dallas-Fort Worth (DFW) Metroplex, a region representing 16 counties, successfully measured daily ozone during 8 weeks of the 1998 high ozone season. It was demonstrated that the concerned public, when properly trained, could successfully operate a large PSD network that requires daily sample handling and weekly mailing procedures, even from remote sites. Data treatment of the 2880 POND measurements included (i) high correlations with collocated continuous monitoring data [ $r$  range = 0.95-0.97], (ii) daily O<sub>3</sub> contour mapping of the 24,000 km<sup>2</sup> area, and (iii) a ranking of O<sub>3</sub> severity in 12 peri-urban counties for guidance in siting additional monitors. With a new 8-h NAAQS standard now in place, a cost-effective network such as POND could aid regional airshed models in generating meaningful guidance for O<sub>3</sub> state implementation plans (SIPs) by providing input that is representative of both rural and urban sites.

Vassal G, Mery-Mignard D, Caulin C. Clinical trials in paediatric oncology. Recommendations for the development of new anticancer agents. *Therapie* 2003; 58(3):229-46.

Abstract: Childhood and adolescent cancers are rare diseases. Despite the progress in treatment (more than two-thirds of all cases are cured), cancer remains the leading cause of death by disease in children older than

1 year. Access to new drugs that are more efficacious or better tolerated is therefore an important public health priority. The objective of our round table was thus to take inventory of the situation and to propose recommendations aimed at facilitating coordinated, rational and more rapid access to new treatments. The active participation of paediatric oncologists, parents, pharmaceutical companies and regulatory authorities proved not only necessary but very constructive. Pharmaceutical companies have developed very few new anticancer agents for children during the past 10 years. The round table identified current trends that appear propitious: the mobilisation of parents and patients' associations; European initiatives to encourage companies to assess drugs in children; regulatory initiatives to guide drug development; and the existence of structured clinical research networks in paediatric oncology, including for the development of early treatment. The round table recommends the following measures to improve access to new treatments for children and adolescents with cancer: 1. Conduct preclinical paediatric evaluation of all anticancer agents that begin the development process for adults (research and validation of treatment targets; pharmacological evaluation in relevant experimental models) to help choose the agents to study in children. 2. Initiate paediatric clinical development before the first application for authorization for adults is filed, when sufficient safety and tolerability data are available, that is, after the phase I trials in adults and optimally during the phase II trials. 3. Optimise paediatric clinical evaluation by defining development plans early and by reducing the duration of studies (enlargement of the early treatment research network to ensure adequate recruitment; new evaluation methods; better extrapolation of pharmacological data from adults to children for dose-finding). 4. Improve information to and participation of parents and patients in clinical research for new treatments. The prerequisite for the success of this project became rapidly clear to all the round-table participants: cooperation and partnership between specialists and other scientists from academia, parent associations, pharmaceutical companies and regulatory authorities. Only with such cooperation can progress in treatment occur and new hopes for recovery be fulfilled.

Vassallo DJ, Hoque F, Roberts MF, Patterson V, Swinfen P, Swinfen R. An evaluation of the first year's experience with a low-cost telemedicine link in Bangladesh. *J Telemed Telecare* 2001; 7(3):125-38. Abstract: In July 1999, the Swinfen Charitable Trust in the UK established a telemedicine link in Bangladesh, between the Centre for the Rehabilitation of the Paralyzed (CRP) in Dhaka and medical consultants abroad. This low-cost telemedicine system used a digital camera to capture still images, which were then transmitted by email. During the first 12 months, 27 telemedicine referrals were made. The following specialties were consulted: neurology (44%),

orthopaedics (40%), rheumatology (8%), nephrology (4%) and paediatrics (4%). Initial email replies were received at the CRP within a day of referral in 70% of cases and within three days in 100%, which shows that store-and-forward telemedicine can be both fast and reliable. Telemedicine consultation was complete within three days in 14 cases (52%) and within three weeks in 24 cases (89%). Referral was judged to be beneficial in 24 cases (89%), the benefits including establishment of the diagnosis, the provision of reassurance to the patient and referring doctor, and a change of management. Four patients (15% of the total) and their families were spared the considerable expense and unnecessary stress of travelling abroad for a second opinion, and the savings from this alone outweighed the set-up and running costs in Bangladesh. The latter are limited to an email account with an Internet service provider and the local-rate telephone call charges from the CRP. This successful telemedicine system is a model for further telemedicine projects in the developing world.

Vaughn BE. Discovering pattern in developing lives: reflections on the Minnesota study of risk and adaptation from birth to adulthood. *Attach Hum Dev* 2005; 7(4):369-80. Abstract: The Minnesota Study of Risk and Adaptation was initiated in the mid-1970s as a short-term longitudinal study of infants at elevated risk for abuse and neglect. At the outset, the project leaders intended to characterize the infant, the caregiving environment, and the larger social milieu of the family in as comprehensive a manner as possible so as to test explicitly posed hypotheses about pathways leading from the child, the caregiving environment, and the social milieu to abuse or neglect. Paradoxically, only a minority of infants recruited to the study were ultimately abused or neglected over the 36-month period for which funding had been provided, but it proved possible to identify several antecedent indicators that predicted their outcome. It was also evident from the data that developmental casualty was elevated in this sample and the frequencies of suboptimal outcomes in social, emotional, and behavioral domains were greater than expected for less stressed samples. The study had yielded a wealth of information about infants and families from this at-risk sample and it was clear that the sample must be followed into childhood so as to describe the trajectories of developmental successes and casualties that were already apparent in the first 24 months of data. Alan Sroufe joined the project leaders in this endeavor and the childhood data supported the study of the sample into adolescence and now into adulthood. At this point, children of the original sample of infants are now being assessed using many of the protocols and procedures used with their parents. The study has produced hundreds of published reports about risk and its consequences, as well as about positive adjustment to life in a socio-cultural milieu that frequently can be

non-supportive or even dangerous. This essay is a reflection on some accomplishments of the Minnesota study as these have helped shape how developmental scientists think about social and emotional development and more generally about how theory has guided the conceptual, empirical, and measurement plans for the study from its beginning.

Vaught W, Fleetwood J. Covert video surveillance in pediatric care. *Hastings Cent Rep* 2002; 32(6):10-1; discussion 11-2.

Veenema TG, Schroeder-Bruce K. The aftermath of violence: children, disaster, and posttraumatic stress disorder. *J Pediatr Health Care* 2002; 16(5):235-44. Abstract: Terrorist attacks, situations of armed conflict, and all forms of catastrophe tax our abilities to cope, understand, and respond. Because of their developmental status, children are even more emotionally vulnerable to the devastating effects of a disaster. When tragedy strikes a family, community, or the nation, helping children cope and regain a sense of safety is critical. A child with posttraumatic stress disorder (PTSD) develops symptoms such as intense fear, disorganized and agitated behavior, emotional numbness, anxiety, or depression after being directly exposed to or witnessing an extreme traumatic situation involving threatened death or serious injury. Victims of repeated abuse or children who live in violent neighborhoods or war zones, or who have witnessed extensive media coverage of violent events, may experience PTSD.

Veenstra G. Income inequality and health. Coastal communities in British Columbia, Canada. *Can J Public Health* 2002; 93(5):374-9. Abstract: OBJECTIVE: An imbalance in the distribution of economic resources, i.e., income inequality, is a characteristic of a community that may influence the aggregate health of the population. In North America, income inequality seems to be strongly related to mortality rates among American communities such as states and metropolitan areas but largely irrelevant for health at similar levels of geopolitical aggregation in Canada. This article summarizes relevant international and North American evidence and then explores relationships between income inequality and mortality rates among coastal communities in the province of British Columbia, Canada. METHODS: Cross-sectional analysis was conducted among twenty-four coastal communities in British Columbia, utilizing four measures based on the 1996 Census to measure income inequality and crude, age-standardized and age- and gender-specific mortality rates averaged over the five-year period 1994-98 to measure health. RESULTS: The three valid measures of income inequality were positively and

significantly related to the crude mortality rate but were not significantly related to the age-standardized mortality rate. Two of the inequality measures were related to mortality rates for males aged 0-44 and for males aged 45-64 before but not after controlling for mean household income. DISCUSSION: Health researchers have yet to report a meaningful relationship between income inequality and population health within Canada. At the risk of committing the ecological fallacy, these findings provisionally support a psychosocial interpretation of the individual-level relationship between income and health wherein members of these communities compare themselves to an encompassing community, e.g., all Canadians.

Vega J, Bedregal P, Jadue L, Delgado I. [Gender inequity in the access to health care in Chile]. *Rev Med Chil* 2003; 131(6):669-78.

Abstract: BACKGROUND: In the last two decades, Chile has experienced advances in economical development and global health indicators. However, gender inequities persist in particular related to access to health services and financing of health insurance. AIM: To examine gender inequities in the access to health care in Chile. MATERIAL AND METHODS: An analysis of data obtained from a serial national survey applied to assess social policies (CASEN) carried out by the Ministry of Planning. During the survey 45,379 and 48,107 dwellings were interviewed in 1994 and in 1998, respectively. RESULTS: Women use health services 1.5 times more often, their salaries are 30% lower in all socioeconomic strata. Besides, in the private health sector, women pay higher insurance premiums than men. Men of less than two years of age have 2.5 times more preventive consultations than girls. This difference, although of lesser magnitude, is also observed in people over 60 years. Women of high income quintiles and users of private health insurance have a better access to preventive consultations but not to specialized care. CONCLUSIONS: An improvement in equitable access of women to health care and financing is recommended. Also, monitoring systems to survey these indicators for women should improve their efficiency.

Vehmas S. Just ignore it? Parents and genetic information. *Theor Med Bioeth* 2001; 22(5):473-84.

Notes: GENERAL NOTE: KIE: Vehmas, Simo  
GENERAL NOTE: KIE: KIE Bib: genetic counseling; genetic screening

Abstract: This paper discusses whether prospective parents ought to find out about their genetic constitution for reproductive reasons. It is argued that ignoring genetic information can be in line with responsible parenthood or perhaps even recommendable. This is because parenthood is essentially an unconditional project in which parents ought to commit themselves to nurturing any kind of child. Besides, the traditional reasons offered for the unfortunateness of impairments and the tragic fate of

families with disabled children are not convincing. Other morally problematic outcomes of genetics, such as discrimination against individuals with impairments, and limiting free parental decision making, are also considered.

Vehmas S. Response to "abortion and assent" by Rosamond Rhodes (CQ Vol 8, No 4) and "abortion, disability, assent, and consent" by Matti Hayry (CQ Vol 10, No 1). Assent and selective abortion: a response to Rhodes and Hayry. *Camb Q Healthc Ethics* 2001; 10(4):433-40.

Velez ML, Jansson LM, Montoya ID, Schweitzer W, Golden A, Sviki D. Parenting knowledge among substance abusing women in treatment. *J Subst Abuse Treat* 2004; 27(3):215-22.

Abstract: The purpose of this study was to assess parenting knowledge and beliefs among drug abusing pregnant and recently postpartum women engaged in a comprehensive substance abuse treatment program. The effects of a parenting skills training program for this population were evaluated. A Parenting Skills Questionnaire was developed and administered to a sample of 73 pregnant and drug-dependent women during their first week of substance abuse treatment and again approximately 7 weeks later, following parenting skills training. The questionnaire was designed to assess whether group and individual parenting sessions changed the subjects' knowledge and beliefs in four parenting domains: newborn care, feeding practices, child development and drug abuse during pregnancy. Pre-intervention scores for all parenting domains were low. Post- vs. pre-intervention comparisons showed significant increases in all domain scores after individual and group parenting skills training. Preliminary results obtained from this clinic-based sample suggest that these substance abusing mothers lacked important parenting knowledge and that this knowledge improved after comprehensive substance abuse treatment that included parenting training.

Velleman R, Templeton L. Alcohol, drugs and the family: results from a long-running research programme within the UK. *Eur Addict Res* 2003; 9(3):103-12.

Notes: CORPORATE NAME: UK Alcohol, Drugs and the Family Research Group

Abstract: This article will outline the main strands of the UK-based Alcohol, Drugs and the Family (ADF) research programme. This programme has examined the impact of substance misuse problems on children, spouses, and families, both in the UK and elsewhere, especially in urban Mexico City and in Australia amongst both urban and rural Aborigine populations. This article will outline the main theoretical perspective that we have developed from this work (the

stress-strain-coping-support model). It will outline some of the key findings of this programme, and address some of the key universals that we have observed across various cultures. It will end by describing current research, including the testing of brief interventions being delivered through primary care to family members to enable them to cope better with the problems which family substance misuse causes.

Vellutino FR, Fletcher JM, Snowling MJ, Scanlon DM. Specific reading disability (dyslexia): what have we learned in the past four decades? *J Child Psychol Psychiatry* 2004; 45(1):2-40.

Abstract: We summarize some of the most important findings from research evaluating the hypothesized causes of specific reading disability ('dyslexia') over the past four decades. After outlining components of reading ability, we discuss manifest causes of reading difficulties, in terms of deficiencies in component reading skills that might lead to such difficulties. The evidence suggests that inadequate facility in word identification due, in most cases, to more basic deficits in alphabetic coding is the basic cause of difficulties in learning to read. We next discuss hypothesized deficiencies in reading-related cognitive abilities as underlying causes of deficiencies in component reading skills. The evidence in these areas suggests that, in most cases, phonological skills deficiencies associated with phonological coding deficits are the probable causes of the disorder rather than visual, semantic, or syntactic deficits, although reading difficulties in some children may be associated with general language deficits. Hypothesized deficits in general learning abilities (e.g., attention, association learning, cross-modal transfer etc.) and low-level sensory deficits have weak validity as causal factors in specific reading disability. These inferences are, by and large, supported by research evaluating the biological foundations of dyslexia. Finally, evidence is presented in support of the idea that many poor readers are impaired because of inadequate instruction or other experiential factors. This does not mean that biological factors are not relevant, because the brain and environment interact to produce the neural networks that support reading acquisition. We conclude with a discussion of the clinical implications of the research findings, focusing on the need for enhanced instruction.

Vemulapalli C, Grady K, Kemp JS. Use of safe cribs and bedroom size among African American infants with a high rate of bed sharing. *Arch Pediatr Adolesc Med* 2004; 158(3):286-9.

Abstract: BACKGROUND: Impoverishment and crowding are associated with an increased risk of sudden unexpected death among infants. Bed sharing likely increases this risk, particularly among African American infants. OBJECTIVES: To compare the sleep environment of African American infants who bed share with that of infants who do not share sleep

surfaces and to compare access to a safe crib, and the space available for it, in the sleeping rooms of both groups of infants. **METHODS:** Home visits were made at approximately age 2 weeks to the homes of serially enrolled African American infants born between July 15, 2001, and November 1, 2001. Questionnaires were used to survey sleep practices, especially sleep surface used. The area of the floor space of rooms used for sleeping was calculated. A portable crib was provided for infants lacking access to safe sleep surfaces. **RESULTS:** Of these infants, 42 (41%) usually bed shared and 60 (59%) slept alone. The areas of the floor spaces were similar (mean +/- SD, 13.8 +/- 3.3 m(2) for bed sharers vs 12.7 +/- 3.7 m(2) for those who slept alone; 95% CI for difference, -0.34 to 2.51 m(2)). Infants sleeping alone were much more likely to have access to a safe crib (51 of 60 vs 13 of 42; P<.001), and 53 cribs were provided. Follow-up telephone calls made at approximately age 7 months to 43.4% of recipients suggested that the cribs were used on most nights, were durable, and were enthusiastically received. **CONCLUSIONS:** Crowding is not a strong explanation for bed sharing among impoverished African American infants in St Louis, Mo, who often bed share because there is not a safe crib available. Providing safe cribs may reduce the prevalence of bed sharing.

Ventura DE, Herbella FA, Schettini ST, Delmonte C. Rapunzel syndrome with a fatal outcome in a neglected child. *J Pediatr Surg* 2005; 40(10):1665-7. Abstract: The "Rapunzel" syndrome (a trichobezoar with a long tail extending from the stomach to the small bowel) is an uncommon disease. It is related to severe complications but rarely associates to a fatal outcome. We report a case of a 5-year-old girl admitted at the emergency department in cardiorespiratory arrest whose autopsy disclosed an ileal perforation that is caused by a long bezoar extending from the stomach to the small bowel. The authors discuss a possible link between Rapunzel syndrome and child neglect.

Verbeke CS, Wenthe U, Grobholz R, Zentgraf H. Fas ligand expression in Hodgkin lymphoma. *Am J Surg Pathol* 2001; 25(3):388-94. Abstract: Because previous investigations suggested involvement of the Fas ligand (FasL) in the selection process in the follicular dendritic cell (FDC)-associated cell cluster of the germinal center, we investigated the

expression of FasL in Hodgkin lymphoma (HL) on protein and RNA level, while considering the Epstein-Barr virus status of the Hodgkin and Reed-Sternberg (HRS) cells. Tumor tissue from 47 patients with classic HL (32 nodular sclerosis [NS], 11 mixed cellularity [MC], and 4 lymphocyte-rich [LR]) was analyzed by immunohistochemistry for FasL, Fas, CD21, and CD23 and by Western blotting for FasL. FasL mRNA was detected by an exon 4-specific oligonucleotide and Epstein-Barr virus infection by in situ hybridization for Epstein-Barr virus early RNAs (EBER). Western blotting showed soluble and membrane-bound forms of FasL. Immunohistochemistry showed FasL expression in virtually all HRS of 94% of NS cases and 82% of MC cases. FasL expression did not correlate with the Epstein-Barr virus status of the HRS. Low FasL protein expression was found in some HRS of LR cases. FasL mRNA was detected in 39% of NS, 46% of MC, and 33% of LR cases. Seventy percent to 90% of the HRS cells expressed Fas. CD21 immunohistochemistry showed disrupted FDC networks in the tumor tissue with reduced and virtually absent expression of CD23 and FasL. These observations suggest that FasL expression in HRS cells and the absence of FasL in the FDC cluster represent a disturbed microenvironment that may be involved in the pathogenesis of HL.

Verburg G, Borthwick B, Bennett B, Rumney P. Online support to facilitate the reintegration of students with brain injury: trials and errors. *NeuroRehabilitation* 2003; 18(2):113-23. Abstract: The reintegration of students after acquired/traumatic brain injury (ABI/TBI) continues to be fraught with difficulties. Presented are (1) case studies exploring the potential of online support for teachers of students with ABI after returning from a paediatric rehabilitation centre; (2) results of Internet-based courses about reintegrating students with ABI; (3) outcomes of videoconferencing-based and Internet email-based support; (4) development of an online support process that uses Questions and Answers as a quick and immediate resource for teachers. The authors recommend that a collaborative process be instituted, in order to generate a relatively small number of high quality online resources about re-integrating students into their school and community. A second recommendation focuses on the development of online support network which may be text or email based or which may use videoconferencing over the Internet. Such networks allow students with ABI to maintain contact with their family and friends in the home community and facilitate their reintegration. An Internet-based support structure also allows professionals to provide consultation, collaboration and continuing input.

Vereecken CA, Keukelier E, Maes L. Influence of mother's educational level on food parenting practices and food habits of young children. *Appetite* 2004; 43(1):93-103. Abstract: The main purpose of the present study is to

examine whether differences in mothers' food parenting practices by educational level could explain differences in food consumption in Flemish preschool children. Three hundred and sixteen mothers of children aged 2.5-7 years, completed a self-administered questionnaire. Differences by educational level were found in children's and mothers' consumption frequencies of fruit, vegetables and soft drinks, and in the use of restrictions, verbal praise, negotiation, discouragement of sweets and restraining from negative modelling behaviour. Multiple logistic regression analyses revealed that mothers' consumption was an independent predictor for all four outcome variables; verbal praise was a significant predictor for children's vegetable consumption, permissiveness for regular consumption of soft drinks and sweets, and, using food as a reward for regular sweet consumption. Differences in children's food consumption by mothers' educational level were completely explained by mother's consumption and other food parenting practices for fruit and vegetables but not for soft drinks.

Vereecken CA, Van Damme W, Maes L. Measuring attitudes, self-efficacy, and social and environmental influences on fruit and vegetable consumption of 11- and 12-year-old children: reliability and validity. *J Am Diet Assoc* 2005; 105(2):257-61. Abstract: This article examines the reliability and construct validity of questions assessing mediating factors of fruit and vegetable consumption among 11- and 12-year-old children (N=207). Internal consistencies were good for most scales, ranging from 0.56 to 0.94. Intraclass correlation coefficients between test and retest were acceptable, ranging from 0.39 to 0.90. Concerning predictive validity, preferences and perceived parental and peer behavior were significantly associated with fruit and vegetable consumption. Self-efficacy in difficult situations and a variety of available fruit were significantly correlated with fruit consumption, while permissive eating practices and obligation rules were significantly correlated with vegetable consumption. General attitudes, outcome expectations, selection efficacy, and encouraging practices were not associated with fruit or vegetable consumption.

Verguts T, Fias W. Representation of number in animals and humans: a neural model. *J Cogn Neurosci* 2004; 16(9):1493-504. Abstract: This article addresses the representation of numerical information conveyed by nonsymbolic and symbolic stimuli. In a first simulation study, we show how number-selective neurons develop when an initially uncommitted neural network is given nonsymbolic stimuli as input (e.g., collections of dots) under unsupervised learning. The resultant network is able to account for the distance and size effects, two ubiquitous effects in numerical cognition. Furthermore, the properties of the network units conform in detail to

the characteristics of recently discovered number-selective neurons. In a second study, we simulate symbol learning by presenting symbolic and nonsymbolic input simultaneously. The same number-selective neurons learn to represent the numerical meaning of symbols. In doing so, they show properties reminiscent of the originally available number-selective neurons, but at the same time, the representational efficiency of the neurons is increased when presented with symbolic input. This finding presents a concrete proposal on the linkage between higher order numerical cognition and more primitive numerical abilities and generates specific predictions on the neural substrate of number processing.

Verma SK, Srivastava DK. A study on mass hysteria (monkey men?) victims in East Delhi. *Indian J Med Sci* 2003; 57(8):355-60. Abstract: During the summer month of May 2001 East Delhi came in grip of an outbreak of mass hysteria. Initial reports alleged that some monkey like creature attacked and caused injuries among number of persons. A medical board was set up to examine and find out the cause of injuries in the victims of the outbreak as a part exercise to apprehend the culprit. The study describes the sociodemographic pattern and injuries observed in these cases. Majority of victims were adult males, belonging to low socioeconomic strata and having low educational level. The incidents occurred mainly during night at the time of power failure. The type, distribution and characteristic of the injuries suggested of their accidental nature. The paper also discusses the role of forensic experts and press in such outbreak.

Verona E, Hicks BM, Patrick CJ. Psychopathy and suicidality in female offenders: mediating influences of personality and abuse. *J Consult Clin Psychol* 2005; 73(6):1065-73. Abstract: The influence of personality and childhood abuse on suicidal behaviors and psychopathy was examined among female prisoners. Scores on the affective/interpersonal component (Factor 1; F1) and the antisocial deviance (Factor 2; F2) component of psychopathy were obtained from the Psychopathy Checklist--Revised (R. D. Hare, 1991). Suicide attempt and childhood physical and sexual abuse history were coded from interviews and prison files, and personality was assessed using the Multidimensional Personality Questionnaire (A. Tellegen, in press). Suicide attempts were positively associated with F2 and negatively associated with F1, and each factor accounted for unique variance in suicidality. Path analyses demonstrated that personality mediated the effects of physical abuse on F2, but sexual abuse accounted for

unique variance in both suicide attempts and F2. Abuse and personality accounted for minimal variance in F1. These results are discussed in relation to the identification of individuals at risk for both self- and other-harm behaviors.

Verona E, Sachs-Ericsson N. The intergenerational transmission of externalizing behaviors in adult participants: the mediating role of childhood abuse. *J Consult Clin Psychol* 2005; 73(6):1135-45. Abstract: Childhood abuse was investigated as a potential mediator of the intergenerational transmission of externalizing behaviors (EXT) in adulthood among a large general population sample drawn from the National Comorbidity Survey. Community participants (N = 5,424) underwent diagnostic and psychosocial interviews and reported on their own adult symptoms of antisocial behavior and substance dependence, parental symptoms, and childhood abuse history. Multiple group structural equation modeling revealed that (a) EXT in parents was associated with childhood abuse in offspring, particularly among mother-daughter dyads, (b) abuse had a unique influence on adult EXT in offspring above parental EXT, and (c) abuse accounted for the relationship between parental EXT and offspring EXT in female but not male participants. This article emphasizes the importance of examining different environmental processes which may explain familial transmission of destructive behaviors in men and women and highlights the importance of family interventions that target parental symptoms to ameliorate risk to offspring.

Vessey JA, Ben-Or K, Mebane DJ *et al.* Evaluating the value of screening for hypertension: an evidence-based approach. *J Sch Nurs* 2001; 17(1):44-9. Abstract: No recommendations regarding in-school blood pressure (BP) screening currently exist. The purpose of this project was to use an evidence-based approach to determine whether BP screening should be initiated as part of one school district's standard screening protocols. Pediatric BP measurement, risk factors for hypertension, issues for determining youth at risk for hypertension, and eligibility criteria for determining conditions appropriate for screening are discussed. BPs of 1st, 6th, and 11th graders were evaluated according to standardized criteria. The evidence indicated that BP screening in school appears warranted, although a formalized study is needed before a definitive decision can be made regarding the incorporation of BP screening into school health services.

Victoria CG, Barros FC. Global child survival initiatives and their relevance to the Latin American and Caribbean Region. *Rev Panam Salud Publica* 2005; 18(3):197-205.

Abstract: We review two series of papers published by *The Lancet*: the Child Survival Series (2003) and the

Neonatal Survival Series (2005). Both series drew attention to the nearly 11 million annual deaths of children under the age of five years, and to the fact that almost 4 million of these deaths occur in the first month of life. We show that two thirds of these deaths could be prevented through universal coverage with existing, low-cost interventions that are failing to reach most children in the world. The series also highlighted the importance of reducing inequities both between and within countries. The relevance of these series to Latin America and the Caribbean is examined. Although substantial progress has been made in reducing mortality and improving coverage, two major challenges remain: how to improve the quality of health interventions, and how to reach the most disadvantaged children in the Latin American and Caribbean Region.

Viljoen DL, Gossage JP, Brooke L *et al.* Fetal alcohol syndrome epidemiology in a South African community: a second study of a very high prevalence area. *J Stud Alcohol* 2005; 66(5):593-604. Abstract: OBJECTIVE: The aim of the study was to determine the prevalence and characteristics of fetal alcohol syndrome (FAS) in a second primary school cohort in a community in South Africa. METHOD: Active case ascertainment, two-tier screening, and Institute of Medicine assessment methodology were employed among 857 first grade pupils, most born in 1993. Characteristics of children with FAS were contrasted with characteristics of a randomly selected control group from the same classrooms. Physical growth and development, dysmorphology and psychological characteristics of the children and measures of maternal alcohol use and smoking were analyzed. RESULTS: The rate of FAS found in this study is the highest yet reported in any overall community in the world, 65.2-74.2 per 1,000 children in the first grade population. These rates are 33-148 times greater than U.S. estimates and higher than in a previous cohort study in this same community (40.5-46.4 per 1,000). Detailed documentation of physical features indicates that FAS children in South Africa have characteristics similar to those elsewhere: poor growth and development, facial and limb dysmorphology, and lower intellectual functioning. Frequent, severe episodic drinking of beer and wine is common among mothers and fathers of FAS children. Their lives are characterized by serious familial, social and economic challenges, compared with controls. Heavy episodic maternal drinking is significantly

associated with negative outcomes of children in the area of nonverbal intelligence but even more so in verbal intelligence, behavior and overall dysmorphology (physical anomalies). Significantly more FAS exists among children of women who were rural residents (odds ratio: 7.36, 95% confidence interval: 3.31-16.52), usually among workers on local farms. CONCLUSION: A high rate of FAS was documented in this community. Given social and economic similarities and racial admixture, we suspect that other communities in the Western Cape have rates that also are quite high.

Villarreal LR. California's Healthy Start: A solid platform for promoting youth development. *New Dir Youth Dev* 2005; (107):89-97, table of contents. Abstract: A school in Los Angeles County reports absences down by 30 percent and disciplinary actions down by 10 percent. A town near Fresno reports having 99 percent of their new kindergartners ready to start school on the first day of class because their immunization and school readiness outreach was so thorough. A school in San Diego reports youth tobacco use down from 15 percent to 3 percent, absences down by 10 percent, and detentions down by over 50 percent. Schools in Humboldt report a 30 percent improvement in math scores and a 40 percent improvement in reading scores. Young adults report that the assistance they received as teens through their school's Healthy Start program saved their lives and enabled them to be successful parents today. These are results from one of California's most successful education mandates-SB620 1991-California's Healthy Start.

Vimpani G. Getting the mix right: family, community and social policy interventions to improve outcomes for young people at risk of substance misuse. *Drug Alcohol Rev* 2005; 24(2):111-25. Abstract: Societal responses to the existence of substance misuse fluctuate between harm minimisation and prohibition. Both approaches are predominantly downstream reactions to substance misuse that focus on the supply of harmful substances and the containment of misuse through treatment, rehabilitation or punishment. Until recently, little attention has been paid to the upstream individual, family, relationship, community or societal antecedents of substance misuse (which often overlap with those for other adverse life outcomes, such as unemployment, antisocial personality disorder and mental health problems) that have operated during earlier life. A growing body of evidence highlights the overlapping biological and experiential antecedents for substance abuse and other poor outcomes as well as the trajectory-changing protective factors that can prevent risks being translated into destiny. Risk minimisation and protection enhancement embedded in family and social systems are the essential building blocks of a set of early intervention strategies that begin antenatally and continue through the developing years of childhood,

adolescence and young adult life, that have been shown to be effective in improving many outcomes in development, health and well-being. Much remains to be done to enable the promise of effective universal and targeted early intervention to be translated into policies, programs and practices that could be life-changing for citizens bogged in the mire of substance misuse and their children. Realistic, timely investment, influenced by the best scientific evidence indicating what works, for whom, under what circumstances, an increased degree of collaboration within and between governments and their agencies to enable "whole of government" responses in partnership with community-based initiatives are essential along with investments in multidisciplinary program evaluation research that will enable evidence-informed policy decisions to be tailored to the needs of individual countries.

Vinchon M, Defoort-Dhellemmes S, Noule N, Duhem R, Dhellemmes P. [Accidental or non-accidental brain injury in infants. Prospective study of 88 cases]. *Presse Med* 2004; 33(17):1174-9. Abstract: OBJECTIVE: To study the epidemiology of head injury (HI) in infants, the factors favouring the occurrence of a subdural haematoma (SDH), the prevalence of retinal haemorrhages (RH) and the prognostic factors, by comparing the non-accidental (NAHI) and accidental (AHI) head injuries. RH, in particular, are of fundamental value in the diagnosis of NAHI but, in the absence of systematic studies, their sensitivity and specificity for the diagnosis of the NAHI have rarely been assessed. METHOD: We prospectively collected the clinical, ophthalmologic and radiological data of HI occurring in children under 24 months old, notably by distinguishing essential macrocrania and symptomatic macrocrania of an SDH, by classifying the HI according to its severity. RESULTS: We observed 88 cases over a period of 22 months. It 28 cases it was NAHI and in the 60 others, AHI. The SDH was often correlated with the presence of retinal haemorrhages and the absence of signs of cranial impact, but not with child abuse or with essential macrocrania. The RH were of great importance in the diagnosis of NAHI; however, non-severe RH was noted in 4 cases of AHI. The neurological prognosis was essentially correlated with the initial clinical severity. CONCLUSION: Although only representing 33% of cases, child abuse was responsible for 2/3 of the deaths and for the totality of the severe morbidity in our series. The infants exhibiting perinatal problems represented an important group at risk of abuse, which justified their regular medical-social follow-up.

Vinter A, Perruchet P. Implicit motor learning through observational training in adults and children. *Mem Cognit* 2002; 30(2):256-61. Abstract: Although evidence of implicit motor learning on the basis of observation alone has been reported, there is some data to suggest that the phenomenon

could be contaminated by the intentional exploitation of explicit knowledge. In the present experiment, a special procedure was adapted to study observational learning in a situation involving the acquisition of a new drawing behavior. The participants consisted of adults and children 6-10 years of age. The results provide support for the view that overt motor practice is not strictly necessary for implicit motor learning. They demonstrate that children display capacities similar to those of adults in this form of learning. Some suggestions are made to account for the contradictory results present in this area of research.

Visitsunthorn N, Durongpisitkul W, Uoonpan S, Jirapongsananuruk O, Vichyanond P. Medical charge of asthma care in admitted Thai children. *J Med Assoc Thai* 2005; 88 Suppl 8:S16-20. Abstract: BACKGROUND: Asthma is one of the most common chronic diseases in children. Due to high admission rate for acute asthmatic attack, children often miss their schools and parents have to stop working to take care of them. These affect both mental and physical health as well as socioeconomic status of the family and the country. OBJECTIVES: To evaluate medical charge of asthma care in children admitted to the Department of Pediatrics, Faculty of Medicine Siriraj Hospital, Mahidol University. MATERIAL AND METHOD: The study was a retrospective and descriptive study. Data were collected from children with asthmatic attack admitted to the Department of Pediatrics, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand from January 1st, 2000 to June 30th, 2003. Cost of room, food, drugs, devices, laboratory study and service charge were recorded. Total medical charges per year, per patient per admission and per patient per day were calculated. Data were analyzed with Chi square test, ANOVA and Post Hoc test. A p value of < 0.05 was considered statistical significant. RESULTS: Numbers of children with asthmatic attack admitted to the Department of Pediatrics, Siriraj Hospital increased between 2000-2002 (113,147 and 176 in 2000, 2001, and 2002). Seventy two percent of the patients were < or = 5 years of age. Most were mild intermittent asthma. The average duration of hospitalization was 4 days (95% CI, 3.6-4.3). Average medical charge per patient per admission and per day was 3236.20 and 998.60 Bahts respectively. There was no significant difference in the medical charge per patient among the admitted years. Medical charge of admission was significantly associated with the asthma severity. (p < or = 0.05) CONCLUSION: The rate of admission from asthmatic attack in children at Siriraj Hospital and the total medical charge per year increased between 2000-2002. Nevertheless, medical charge of asthma admission per person was unchanged. Main expense in medical charge of asthma admission was the cost of medication and room. Severity of asthma was related directly to medical charge.

Vizard E, French L, Hickey N, Bladon E. Severe personality disorder emerging in childhood: a proposal for a new developmental disorder. *Crim Behav Ment Health* 2004; 14(1):17-28.

Abstract: BACKGROUND: The concept of 'severe personality disorder' is currently applied to adults with a history of serious antisocial and offending behaviour. There is, however, no similar classification that can be applied to the sub-group of children and adolescents who display persistent and serious offending from an early age. This omission from diagnostic nomenclature prevents the appropriate early identification, assessment and management of these young people. METHOD: This paper therefore proposes a new developmental disorder: 'severe personality disorder emerging in childhood'. The existing evidence base strongly supports the presence of a developmental trajectory from childhood to adult life for the small number of children who show early signs of severe personality disorder (SPD). Based on a review of the literature and the experience of working in a specialist, forensic Child and Adolescent Mental Health Service (CAMHS), a multi-factorial model is proposed that outlines the developmental trajectory of SPD. This model includes neurobiological, psychosocial, environmental and systemic factors, within a developmental framework, and contributes to a more developmentally appropriate understanding of the genesis of severe personality disorder.

Voges MA, Romney DM. Risk and resiliency factors in posttraumatic stress disorder. *Ann Gen Hosp Psychiatry* 2003; 2(1):4.

Abstract: BACKGROUND: Not everyone who experiences a trauma develops posttraumatic stress disorder (PTSD). The aim of this study was to determine the risk and resiliency factors for this disorder in a sample of people exposed to trauma. METHOD: Twenty-five people who had developed PTSD following a trauma and 27 people who had not were asked to complete the Posttraumatic Stress Diagnostic Scale, the Coping Inventory for Stressful Situations, and the State-Trait Anxiety Inventory. In addition, they completed a questionnaire to provide information autobiographic and other information. ANALYSIS: Five variables that discriminated significantly between the two groups using chi-square analysis or t-tests were entered into a logistic regression equation as predictors, namely, being female, perceiving a threat to one's life, having a history of sexual abuse, talking to someone about the event, and the "intentionality" of the trauma. RESULTS: Only being female and perceiving a threat to one's life were significant predictors of PTSD. Taking base rates into account, 96.0% of participants with PTSD were correctly classified as having the disorder and 37.0% of participants without PTSD were correctly classified as not having the disorder, for an overall success rate of 65.4% CONCLUSIONS: Because women are more likely than men to develop

PTSD, more preventive measures should be directed towards them. The same is true for trauma victims (of both sexes) who feel that their life was in danger

- Vogler SD, Davidson AJ, Crane LA, Steiner JF, Brown JM. Can paraprofessional home visitation enhance early intervention service delivery? *J Dev Behav Pediatr* 2002; 23(4):208-16. Abstract: A 1-year randomized trial compared intensive case management (ICM) versus basic case management (BCM) in facilitating early intervention (EI) service use among children in an urban health system. Of 159 participating families with delayed or at-risk preschool-aged children, 88 received ICM from paraprofessionals versus 71 families who received less comprehensive BCM from a nurse. In the ICM versus BCM group, a shorter interval to assessment (98 vs 140 d,  $p = .05$ ) but similar assessment rate (86% vs 80%,  $p = .29$ ) was observed. The ICM group had more services recommended per child (1.64 vs 1.16,  $p < .004$ ) and initiated (1.20 vs 0.85,  $p < .04$ ). There was no difference in median time to EI program initiation for ICM versus BCM (228 vs 200 d,  $p = .88$ ) or initiation and visit compliance rate for EI services. Specific efforts to improve outcomes (e.g., decrease initiation time and increase use of EI services) are still needed.
- Volmer M, de Vries JC, Goldschmidt HM. Infrared analysis of urinary calculi by a single reflection accessory and a neural network interpretation algorithm. *Clin Chem* 2001; 47(7):1287-96. Abstract: BACKGROUND: Preparation of KBr tablets, used for Fourier transform infrared (FT-IR) analysis of urinary calculus composition, is time-consuming and often hampered by pellet breakage. We developed a new FT-IR method for urinary calculus analysis. This method makes use of a Golden Gate Single Reflection Diamond Attenuated Total Reflection sample holder, a computer library, and an artificial neural network (ANN) for spectral interpretation. METHODS: The library was prepared from 25 pure components and 236 binary and ternary mixtures of the 8 most commonly occurring components. The ANN was trained and validated with 248 similar mixtures and tested with 92 patient samples, respectively. RESULTS: The optimum ANN model yielded root mean square errors of 1.5% and 2.3% for the training and validation sets, respectively. Fourteen simple expert rules were added to correct systematic network inaccuracies. Results of 92 consecutive patient samples were compared with those of a FT-IR method with KBr tablets, based on an initial computerized library search followed by visual inspection. The bias was significantly different from zero for brushite (-0.8%) and the concomitantly occurring whewellite (-2.8%) and weddellite (3.8%), but not for ammonium hydrogen urate (-0.1%), carbonate apatite (0.5%), cystine (0.0%), struvite (0.4%), and uric acid (-0.1%). The 95% level of agreement of all results was 9%. CONCLUSIONS: The new Golden Gate method is superior because of its

smaller sample size, user-friendliness, robustness, and speed. Expert knowledge for spectral interpretation is minimized by the combination of a library search and ANN prediction, but visual inspection remains necessary.

- von Salis T. ["Violence and psychotherapy": what transfers? Some experiences in private practice]. *Rev Med Suisse Romande* 2001; 121(7):517-20.
- Vora A, Makris M. Personal practice: An approach to investigation of easy bruising. *Arch Dis Child* 2001; 84(6):488-91.
- Vostanis P. Patients as parents and young people approaching adulthood: how should we manage the interface between mental health services for young people and adults? *Curr Opin Psychiatry* 2005; 18(4):449-54. Abstract: PURPOSE OF REVIEW: The present review discusses critically recent research findings (published during the period 2003-2004) on the mental health needs of young people in transition (old adolescents and young adults), including those of young parents. Also, the evidence on effective interventions and service models is considered. RECENT FINDINGS: Emerging evidence indicates that young people have high rates of mental health needs (in addition to high prevalence of psychiatric disorders) that may be related to life transitions. These needs often fall between the remit of adolescent/adult and mental health/social care services, and therefore are not adequately met. With the exception of mental health interventions for early psychosis and psychosocial programmes for teenage parents, there is very limited knowledge on how best to meet the mental health needs of young people in transition. SUMMARY: It is widely recognized that young people in transition require services and interventions tailored to their characteristics, rather than a mere extension to either child/adolescent or adult services. Recent policies and research findings have led to the development of early psychosis interventions, with initial encouraging messages. Similar initiatives are required for young people with nonpsychotic disorders.

- Votruba-Drzal E, Coley RL, Chase-Lansdale PL. Child care and low-income children's development: direct and moderated effects. *Child Dev* 2004; 75(1):296-312. Abstract: A large literature has documented the influence of child care on young children's development, but few studies have examined low-income children in community care arrangements. Using data from Welfare, Children, and Families: A Three-City Study (N = 204), this study examined the influence of child care quality and the extent of care on low-income children's (ages 2-4 years) cognitive and socioemotional development over time. Higher levels of child care quality were modestly associated with

improvements in children's socioemotional development, and extensive hours in child care were linked to increases in children's quantitative skills and decreases in behavior problems. Analyses suggest that child care quality may be particularly salient for subgroups of children from low-income families.

Vythilingam M, Heim C, Newport J *et al.* Childhood trauma associated with smaller hippocampal volume in women with major depression. *Am J Psychiatry* 2002; 159(12):2072-80.

Abstract: **OBJECTIVE:** Smaller hippocampal volume has been reported only in some but not all studies of unipolar major depressive disorder. Severe stress early in life has also been associated with smaller hippocampal volume and with persistent changes in the hypothalamic-pituitary-adrenal axis. However, prior hippocampal morphometric studies in depressed patients have neither reported nor controlled for a history of early childhood trauma. In this study, the volumes of the hippocampus and of control brain regions were measured in depressed women with and without childhood abuse and in healthy nonabused comparison subjects. **METHOD:** Study participants were 32 women with current unipolar major depressive disorder-21 with a history of prepubertal physical and/or sexual abuse and 11 without a history of prepubertal abuse-and 14 healthy nonabused female volunteers. The volumes of the whole hippocampus, temporal lobe, and whole brain were measured on coronal MRI scans by a single rater who was blind to the subjects' diagnoses. **RESULTS:** The depressed subjects with childhood abuse had an 18% smaller mean left hippocampal volume than the nonabused depressed subjects and a 15% smaller mean left hippocampal volume than the healthy subjects. Right hippocampal volume was similar across the three groups. The right and left hippocampal volumes in the depressed women without abuse were similar to those in the healthy subjects. **CONCLUSIONS:** A smaller hippocampal volume in adult women with major depressive disorder was observed exclusively in those who had a history of severe and prolonged physical and/or sexual abuse in childhood. An unreported history of childhood abuse in depressed subjects could in part explain the inconsistencies in hippocampal volume findings in prior studies in major depressive disorder.

Wade TD, Kendler KS. Parent, child, and social correlates of parental discipline style: a retrospective, multi-informant investigation with female twins. *Soc Psychiatry Psychiatr Epidemiol* 2001; 36(4):177-85. Abstract: **BACKGROUND:** The type of parental discipline used in families appears to be related to parental characteristics, child temperament, and aspects of the social context. Within these three areas, we examine specific correlates of parental discipline (namely, limit setting and physical discipline) using a multiple informant model. **METHOD:** Using interview

data from 2003 female twins from a population-based twin registry and 1472 of their parents, we examined retrospective reports of parental discipline from three perspectives. First, father and mother reporting separately on the type of discipline they provided for their offspring; second, each twin reporting on the type of discipline they received from their parents; and third, each parent reporting on the discipline provided by their spouse. Using a mixed model regression, we examined the impact on parental discipline of 25 potential predictor variables, as reported by parents, from three domains: social context, parental factors, and childhood vulnerability factors. **RESULTS:** There was a great deal of overlap between the independent variables for the two types of discipline in the areas of child vulnerability factors and family relationships, with similar effect sizes for child disobedience, teenage rebelliousness, and family discord. However, the profiles of parental characteristics associated with each type of discipline were quite different. Greater use of physical discipline was associated with less parental warmth, a higher incidence of parental lifetime generalised anxiety disorder, and more frequent religious attendance. Greater use of limit setting was associated with more years of parental education, younger age, and greater parental extroversion and authoritarianism. **CONCLUSIONS:** Parental characteristics, child temperament, and social context may all contribute to the frequency of discipline used in families, but parental characteristics may be most influential in determining the type of discipline used.

Wadonda-Kabondo N, Sterne JA, Golding J, Kennedy CT, Archer CB, Dunnill MG. A prospective study of the prevalence and incidence of atopic dermatitis in children aged 0-42 months. *Br J Dermatol* 2003; 149(5):1023-8.

Notes: **CORPORATE NAME:** ALSPAC Study Team Abstract: **BACKGROUND:** There is strong evidence that the incidence and prevalence of atopic diseases is increasing. However, estimates of the prevalence of atopic dermatitis (AD) have varied greatly in the U.K. and most parts of the developed world. **OBJECTIVES:** The aim of the study was to estimate the prevalence and incidence of AD between the ages of 0 and 42 months in children born in the 1990s in a defined population in the U.K. **DESIGN:** We used data from the Avon Longitudinal Study of Pregnancy and Childhood (ALSPAC), a large population-based study in the U.K. that enrolled all pregnant mothers who were resident in Avon and had their delivery date falling between 1 April 1991 and 31 December 1992. Since then ALSPAC has collected a wide range of data from the newborns and their parents. Data reported here were collected at 6, 18, 30 and 42 months using parental reports in a postal questionnaire. Of the 14 009 children originally enrolled 8530 provided information on AD in each of the four follow-up questionnaires. We defined AD as a report of rash in at least two of the four questionnaires. Incidence risk was defined as the

percentage of new cases of AD between follow-up questionnaires, out of the total number of children whose parents had not reported that they had AD by the time of the previous follow-up. RESULTS: Period prevalence of 21.0%, 25.6%, 23.2% and 19.9% were observed at ages 0-6, 6-18, 18-30 and 30-42 months, respectively. The corresponding incidence risks were 21.0%, 11.2% and 3.8%, at 0-6, 6-18 and 18-30 months, respectively. There were no gender differences in either the incidence or prevalence of the disease. CONCLUSIONS: Results from this large, prospective study are consistent with recent reports of increased incidence and prevalence of AD. Health planners can use our estimates of incidence and prevalence to project the number of children likely to suffer from AD during infancy and early childhood, and thus to determine the human and financial resources required.

Wahid ST, Nag S, Bilous RW, Marshall SM, Robinson AC. Audit of influenza and pneumococcal vaccination uptake in diabetic patients attending secondary care in the Northern Region. *Diabet Med* 2001; 18(7):599-603. Abstract: AIMS: To document uptake of influenza and pneumococcal vaccination in diabetic patients attending secondary care in the Northern Region, and to explore influencing factors. METHODS: Diabetic patients attending out-patients in Middlesbrough, Gateshead and Newcastle were questioned from October 1999 to March 2000. Physicians inquired about influenza and pneumococcal vaccination status using a standardized questionnaire. Data collected included age, year of diagnosis, duration of diabetes, type of diabetes, and the presence of other recognized indications for vaccination. RESULTS: Two hundred and sixty-eight diabetic patients, 42% (113/268) with Type 1 diabetes, 34% (91/268) with ischaemic heart disease, 10% (26/268) with chronic pulmonary disease (CPD) and 10% (27/268) with chronic renal disease, were questioned. Thirty-five percent (93/268) of patients received both influenza and pneumococcal vaccines, 24% (64/268) received only influenza vaccine, and none received pneumococcal vaccine alone. Most vaccinees received advice about influenza and pneumococcal vaccination from their general practitioner (90% (142/157) and 87% (81/93), respectively). A large number of non-vaccinees were unaware of the need for influenza and pneumococcal vaccination (69% (76/111) and 91% (159/175), respectively). Using multiple logistic regression co-existing CPD increased the odds of receiving influenza (odds ratio (OR) (95% confidence interval (CI)) = 1.99 (1.07-14.12)) or pneumococcal (OR = 3.77 (1.69-

21.76)) vaccination. Furthermore, each 1-year increase in age increased the chance of receiving influenza or pneumococcal vaccination by 22% (OR = 1.22 (1.09-1.67) and 29% (OR = 1.29 (1.07-1.72)), respectively. CONCLUSIONS: Vaccination rates in these diabetic patients are unsatisfactory. Secondary care health professionals might increase rates by raising the topic in consultations. *Diabet. Med.* 18, 599-603 (2001)

Wainryb C, Brehl BA, Matwin S. Being hurt and hurting others: children's narrative accounts and moral judgments of their own interpersonal conflicts. *Monogr Soc Res Child Dev* 2005; 70(3):1-114. Abstract: Children's narrative accounts and moral evaluations of their own interpersonal conflicts with peers were examined. Girls and boys (N = 112) in preschool (M = 4.8 years), first grade (M = 6.9 years), fifth grade (M = 10.9 years), and tenth grade (M = 16.2 years) provided one narrative of a time when they had been hurt by a peer ("victim"), and one of a time when they had hurt a peer ("perpetrator"). Victim and perpetrator narratives were equally long and detailed and depicted similar types of harmful behaviors, but differed significantly in terms of various measures of content and coherence. Narratives given from the victim's perspective featured a self-referential focus and a fairly coherent structure. When the same children gave accounts of situations in which they had been the perpetrators, their construals were less coherent and included multiple shifts between references to their own experience and the experience of the other. Children's moral judgments also varied by perspective, with the majority of victims making negative judgments and nearly half the perpetrators making positive or mixed judgments. These differences in moral judgments were related to the distinct ways in which victims and perpetrators construed conflict situations. Age differences were also found in both narrative construals and moral evaluations, but regardless of their age children construed conflict situations differently from the victim's and the perpetrator's perspectives. By integrating, within the study of moral development, children's interpretations of the social interactions that are at the basis of moral thinking, this approach brings us a step closer to conceptualizing the study of children's moral behavior.

Waisman Y, Aharonson-Daniel L, Mor M, Amir L, Peleg K. The impact of terrorism on children: a two-year experience. *Prehospital Disaster Med* 2003; 18(3):242-8.

Abstract: OBJECTIVES: To review and analyze the cumulative two-year, Israeli experience with medical care for children victims of terrorism during the prehospital and hospital phases. METHODS: Data were collected from the: (1) Magen David Adom National Emergency Medical System Registry (prehospital phase); (2) medical records from the authors' institutions (pediatric triage); and (3) Israel Trauma Registry (injury characteristics and utilization

of in-hospital resources). Statistical analyses were performed as appropriate. **INTRODUCTION:** During the recent wave of violence in Israel and the surrounding region, hundreds of children have been exposed to and injured by terrorist attacks. There is a paucity of data on the epidemiology and management of terror-related trauma in the pediatric population and its effects on the healthcare system. This study focuses on four aspects of terrorism-related injuries: (1) tending to victims in the prehospital phase; (2) triage, with a description of a modified, pediatric triage algorithm; (3) characteristics of trauma-related injuries in children; and (4) utilization of in-hospital resources. **RESULTS:** During the study period, 41 mass-casualty events (MCEs) were managed by Magen David Adom. Each event involved on average, 32 regular and nine mobile intensive care unit ambulances with 93 medics, 19 paramedics, and four physicians. Evacuation time was 5-10 minutes in urban areas and 15-20 minutes in rural areas. In most cases, victims were evacuated to multiple facilities. To improve efficiency and speed, the Magen David Adom introduced the use of well-trained "first-responders" and volunteer, off-duty professionals, in addition to "scoop and run" on-the-scene management. Because of differences in physiology and response between children and adults, a pediatric triage algorithm was developed using four categories instead of the usual three. Analysis of the injuries sustained by the 160 children hospitalized after these events indicates that most were caused by blasts and penetration by foreign objects. Sixty-five percent of the children had multiple injuries, and the proportion of critical to fatal injuries was high (18%). Compared to children with non-terrorism-related injuries, the terrorism-related group had a higher rate of surgical interventions, longer hospital stays, and greater needs for rehabilitation services. **CONCLUSION:** Terrorism-related injuries in children are severe and increase the demand for acute care. The modifications in the management of pediatric casualties from terrorism in Israel may contribute to the level of preparedness of medical and paramedical personnel to cope with future events. Further studies of other aspects of traumatic injuries, such as its short- and long-term psychological consequences, will provide a more comprehensive picture of the damage inflicted on children by acts of terrorism.

Waites C, Macgowan MJ, Pennell J, Carlton-LaNey I, Weil M. Increasing the cultural responsiveness of family group conferencing. *Soc Work* 2004; 49(2):291-300. Abstract: Child welfare struggles to manage child abuse and neglect and to seek permanency for children, while being culturally responsive to the communities it serves. Family group conferencing, piloted in New Zealand and now used in the United States and other countries, is a strengths-based model that brings together families and their support systems to develop and carry out a plan that protects, nurtures, and safeguards children and other family members. This

article describes the model and a culturally competent method for assessing and adapting the model for the African American, Cherokee, and Latino/Hispanic communities in North Carolina.

Waldman HB. Millennium children. *ASDC J Dent Child* 2002; 69(3):332-5, 236.

Abstract: A federal agency's extensive report on the well-being of our children at the beginning of the new millennium provides an opportunity to review the many achievements and remaining concerns about the health and social environment of the children in our communities and in many of our dental practices.

Walker SP, Chang SM, Powell CA, Grantham-McGregor SM. Psychosocial intervention improves the development of term low-birth-weight infants. *J Nutr* 2004; 134(6):1417-23.

Abstract: It is estimated that 11% of births in developing countries are term low-birth-weight (LBW); however, there is limited information on the development of these infants. Our objectives were to determine the effect of psychosocial intervention on the development of LBW infants and to compare term LBW and normal-birth-weight (NBW) infants. Term LBW (n = 140) and NBW infants (n = 94) were enrolled from the main maternity hospital in Kingston, Jamaica. The LBW infants were randomly assigned to control or intervention comprising weekly home visits from birth to 8 wk and from 7 to 24 mo of age. Development was assessed at 15 and 24 mo with the Griffiths Scales. The intervention benefited the infants' developmental quotient (DQ,  $P < 0.05$ ) and performance subscale at 15 mo ( $P < 0.02$ ), the hand and eye ( $P < 0.05$ ) and performance subscales ( $P < 0.02$ ) at 24 mo, and home environment at 12 mo. The effect of the intervention on development was mediated in part by the improvement in the home environment. The control LBW infants had significantly lower scores than the NBW in DQ and several subscales, whereas there were no significant differences between the NBW and the LBW infants after intervention. In conclusion, term LBW was associated with developmental delays, which were reduced with psychosocial intervention.

Wall A, Scowen P. After Victoria: the outcome of the Victoria Climbié inquiry. *J Fam Health Care* 2003; 13(3):61-2.

Wall R, Cunningham P, Walsh P, Byrne S. Explaining the output of ensembles in medical decision support on a case by case basis. *Artif Intell Med* 2003; 28(2):191-206.

Abstract: The use of ensembles in machine learning

(ML) has had a considerable impact in increasing the accuracy and stability of predictors. This increase in accuracy has come at the cost of comprehensibility as, by definition, an ensemble model is considerably more complex than its component models. This is of significance for decision support systems in medicine because of the reluctance to use models that are essentially black boxes. Work on making ensembles comprehensible has so far focused on global models that mirror the behaviour of the ensemble as closely as possible. With such global models there is a clear tradeoff between comprehensibility and fidelity. In this paper, we pursue another tack, looking at local comprehensibility where the output of the ensemble is explained on a case-by-case basis. We argue that this meets the requirements of medical decision support systems. The approach presented here identifies the ensemble members that best fit the case in question and presents the behaviour of these in explanation.

Wall TC, Brumfield CG, Cliver SP, Hou J, Ashworth CS, Norris MJ. Does early discharge with nurse home visits affect adequacy of newborn metabolic screening? *J Pediatr* 2003; 143(2):213-8. Abstract: OBJECTIVE: To examine the impact of early discharge on newborn metabolic screening. STUDY DESIGN: Metabolic screening results were obtained from the Alabama State Lab for all infants born at our hospital between 8/1/97, and 1/31/99, and were matched with an existing database of early discharge infants. An early newborn discharge was defined as a discharge between 24 and 47 hours of age. Metabolic screening tests included phenylketonuria (PKU), hypothyroidism, and congenital adrenal hyperplasia (CAH). Early discharge and traditional stay infants were compared to determine the percentage of newborns screened and the timing of the first adequate specimen. RESULTS: The state laboratory received specimens from 3860 infants; 1324 were on early discharge newborns and 2536 infants in the traditional stay group. At least one filter paper test (PKU, hypothyroidism, and CAH) was collected on 99.2% of early discharge infants and 96.0% of traditional stay infants ( $P < .0001$ ). Early discharge infants had a higher rate of initial filter paper specimens being inadequate (22.9%) compared with traditional stay infants (14.3%,  $P < .0001$ ) but had a higher rate of repeat specimens when the initial specimen was inadequate (85.0% early discharge vs 75.3% traditional stay,  $P = .002$ ). The early discharge group was more likely to have an adequate specimen within the first 9 days of life (1001, 98.8% early discharge vs 2016, 96.7% traditional stay,  $P = .0005$ ). CONCLUSIONS: In this well established early discharge program with nurse home visits, newborn metabolic screening is not compromised by early discharge.

Wallace PS, Whishaw IQ. Independent digit movements and precision grip patterns in 1-5-month-old human infants: hand-babbling, including vacuous then self-directed

hand and digit movements, precedes targeted reaching. *Neuropsychologia* 2003; 41(14):1912-8. Abstract: Previous work has described human reflexive grasp patterns in early infancy and visually guided reaching and grasping in late infancy. There has been no examination of hand movements in the intervening period. This was the purpose of the present study. We video recorded the spontaneous hand and digit movements made by alert infants over their first 5 months of age. Over this period, spontaneous hand and digit movements developed from fists to almost continuous, vacuous movements and then to self-directed grasping movements. Amongst the many hand and digit movements observed, four grasping patterns emerged during this period: fists, pre-precision grips associated with numerous digit postures, precision grips including the pincer grasp, and self-directed grasps. The finding that a wide range of independent digit movements and grasp patterns are displayed spontaneously by infants within their first 5 months of age is discussed in relation to the development of the motor system, including the suggestion that direct connections of the pyramidal tract are functional relatively early in infancy. It is also suggested that hand babbling, consisting of first vacuous and then self-directed movements, is preparatory to targeted reaching.

Wallace RH, Marini C, Petrou S *et al.* Mutant GABA(A) receptor gamma2-subunit in childhood absence epilepsy and febrile seizures. *Nat Genet* 2001; 28(1):49-52.

Abstract: Epilepsies affect at least 2% of the population at some time in life, and many forms have genetic determinants. We have found a mutation in a gene encoding a GABA(A) receptor subunit in a large family with epilepsy. The two main phenotypes were childhood absence epilepsy (CAE) and febrile seizures (FS). There is a recognized genetic relationship between FS and CAE, yet the two syndromes have different ages of onset, and the physiology of absences and convulsions is distinct. This suggests the mutation has age-dependent effects on different neuronal networks that influence the expression of these clinically distinct, but genetically related, epilepsy phenotypes. We found that the mutation in GABRG2 (encoding the gamma2-subunit) abolished in vitro sensitivity to diazepam, raising the possibility that endozepines do in fact exist and have a physiological role in preventing seizures.

Walline JJ, Holden BA, Bullimore MA *et al.* The current state of corneal reshaping. *Eye Contact Lens* 2005; 31(5):209-14.

**Abstract:** **PURPOSE:** The application of contact lenses to alter the shape of the cornea and temporarily reduce or eliminate myopia is known as orthokeratology, corneal refractive therapy, or corneal reshaping. It was first introduced in the 1960s, but high oxygen permeable materials and more sophisticated designs allow patients to wear contact lenses only during sleep, while dramatically improving the predictability and rate of myopia reduction. Many studies have shown that most corneal reshaping patients achieve uncorrected visual acuity of 20/25 or better that lasts all day long in one to two weeks of nighttime wear. Treatment is primarily effective through central epithelial thinning and midperipheral epithelial and stromal thickening. Much remains to be learned about corneal reshaping contact lenses and their effects on the cornea. **METHODS:** The authors reviewed existing knowledge and determined what needs to be learned in order to provide patients with appropriate informed consent prior to corneal reshaping contact lens wear. **RESULTS:** While corneal reshaping contact lenses are effective at temporarily reducing or eliminating myopia, claims about the progress of myopia being controlled with corneal reshaping contact lenses should not be made until further studies are published in peer-reviewed literature. The incidence and prevalence of microbial keratitis related to corneal reshaping contact lens wear is not known. Any overnight wear of contact lenses increases the risk of infection, but it is not known whether the risks of microbial keratitis are greater for corneal reshaping overnight contact lens wearers than other form of overnight contact lens wear. It is also not known whether the risk of microbial keratitis is greater for children than adults, but we must determine if children are at greater risk than adults because many children are wearing corneal reshaping contact lenses. **CONCLUSIONS:** Finally, it is recommended that ongoing education be provided to practitioners and staff regarding safety, informed consent, and prevention of potential problems, with special emphasis on the critical need to properly and thoroughly disinfect lenses that will be worn overnight.

Walrath CM, Mandell DS, Liao Q *et al.* Suicide attempts in the "comprehensive community mental health services for children and their families" program. *J Am Acad Child Adolesc Psychiatry* 2001; 40(10):1197-205. **Abstract:** **OBJECTIVE:** To compare clinical characteristics of youths who had attempted suicide recently, previously but not recently, repeatedly, or never. **METHOD:** The sample comprised 4,677 youths receiving services between 1993 to 1998 in 22 communities and participating in the national evaluation of the Comprehensive Community Mental Health Services for Children and Their Families Program. Data on suicide attempts, demographics, and clinical characteristics were obtained from intake

interviews and referring agencies. Chi-square and univariate analyses of variance were used for between-group comparisons. **RESULTS:** Twenty-one percent of the sample had a history of attempted suicide. Previous and repeat attempters were more likely to have a history of family violence and substance abuse. Repeat attempters were most likely to have depression, while never and previous (but not recent) attempters were more likely to have conduct disorder. Other clinical differences were also found. **CONCLUSIONS:** Among children receiving mental health services, those who attempt suicide experience more and different types of distress, depending on the recency and frequency of attempts. Clinicians should be aware that depression is not a necessary factor in predicting suicide attempts and that suicide risk is also associated with violent and aggressive behaviors.

Walsh C, Ross LF. Are minority children under- or overrepresented in pediatric research? *Pediatrics* 2003; 112(4):890-5.

**Abstract:** **OBJECTIVES:** There is extensive documentation that minority adults are underrepresented in medical research, but there are scant data regarding minority children and their parents. **METHODS:** All full-length articles published in the paper edition of 3 general pediatric journals between July 1999 and June 2000 were collected and reviewed. Articles were excluded when they did not include at least 1 US researcher, all subjects at US institutions, parents or children as subjects, some prospective data collection, or between 8 and 10 000 subjects. We recorded the number and race/ethnicity (R/E) of all subjects, the type of research, and the type of data collected. Corresponding authors were surveyed to clarify R/E data. **RESULTS:** A total of 192 studies qualified. R/E data were reported in 114 (59%) studies, and survey data provided additional or new information in 25 studies resulting in R/E data in 128 (67%) articles accounting for 75% of the subjects. R/E was described by >10 different labels. There was an overrepresentation of black subjects and an underrepresentation of white and Hispanic subjects compared with the census data. When compared with research participation of child subjects, generally, black children were overrepresented and Hispanic children were underrepresented in clinical trials, and both were underrepresented in therapeutic research. Black and Hispanic children were overrepresented in potentially stigmatizing research. **CONCLUSIONS:** Overall, we found an overrepresentation of black subjects and an underrepresentation of white and Hispanic subjects with significant variations depending on the type of research.

Walsh P, Cunningham P, Rothenberg SJ, O'Doherty S, Hoey H, Healy R. An artificial neural network ensemble to predict disposition and length of stay in children presenting with bronchiolitis. *Eur J Emerg Med* 2004; 11(5):259-64.

Abstract: **BACKGROUND:** Artificial neural networks apply complex non-linear functions to pattern recognition problems. An ensemble is a 'committee' of neural networks that usually outperforms single neural networks. Bronchiolitis is a common manifestation of viral lower respiratory tract infection in infants and toddlers. **OBJECTIVE:** To train artificial neural network ensembles to predict the disposition and length of stay in children presenting to the Emergency Department with bronchiolitis. **METHODS:** A specifically constructed database of 119 episodes of bronchiolitis was used to train, validate, and test a neural network ensemble. We used EasyNN 7.0 on a 200 Mhz pentium PC with a maths co-processor. The ensemble of neural networks constructed was subjected to fivefold validation. Comparison with actual and predicted dispositions was measured using the kappa statistic for disposition and the Kaplan-Meier estimations and log rank test for predictions of length of stay. **RESULTS:** The neural network ensembles correctly predicted disposition in 81% (range 75-90%) of test cases. When compared with actual disposition the neural network performed similarly to a logistic regression model and significantly better than various 'dumb machine' strategies with which we compared it. The prediction of length of stay was poorer, 65% (range 60-80%), but the difference between observed and predicted lengths of stay were not significantly different. **CONCLUSION:** Artificial neural network ensembles can predict disposition for infants and toddlers with bronchiolitis; however, the prediction of length of hospital stay is not as good.

Walter AJ. Misdiagnosis of abuse. *CMAJ* 2003; 169(7):651-2; author reply 652.

Walton MK. Advocacy and leadership when parental rights and child welfare collide: the role of the advanced practice nurse. *J Pediatr Nurs* 2002; 17(1):49-58. Abstract: This article describes the experience of an advanced practice nurse in a challenging clinical situation. A mother with mental illness and mental retardation seeks to retain parental rights and care for her newborn with cystic fibrosis. The nurse provides leadership to the hospital team and serves as an advocate throughout legal proceedings. A systematic, nonjudgmental, and empathic approach to gathering information, working with the family, welfare, and legal representatives is described. Enacting a complex and court-mandated homecare education regimen to the disabled mother is discussed. Preparation to testify in a termination of parental rights proceeding is outlined and a summary description of the testimony provided.

Walton-Moss BJ, Campbell JC. Intimate partner violence: implications for nursing. *Online J Issues Nurs* 2002; 7(1):6.

Abstract: Intimate partner violence is responsible for 30% of female homicides in the U. S. and has multiple

negative health consequences. It is identified as one of the objectives in Healthy People 2010. Women are more likely to be assaulted by a current or former intimate partner than an acquaintance, family member, friend, or stranger. Universal screening is advocated as an effective approach in identifying affected women. There exists a few states mandating report of women with injuries resulting from IPV but it is only clearly mandated in California. Interventions to address the problem include those focused on increasing identification and screening, and treatment of intimate partner violence. This paper reviews the epidemiology, identification and screening, and interventions for IPV. The role for nursing is discussed concluding with directions for further investigation.

Wandersman A, Florin P. Community interventions and effective prevention. *Am Psychol* 2003; 58(6-7):441-8. Abstract: The prevalence of pregnancy, substance abuse, violence, and delinquency among young people is unacceptably high. Interventions for preventing problems in large numbers of youth require more than individual psychological interventions. Successful interventions include the involvement of prevention practitioners and community residents in community-level interventions. The potential of community-level interventions is illustrated by a number of successful studies. However, more inclusive reviews and multisite comparisons show that although there have been successes, many interventions did not demonstrate results. The road to greater success includes prevention science and newer community-centered models of accountability and technical assistance systems for prevention.

Wang AT, Dapretto M, Hariri AR, Sigman M, Bookheimer SY. Neural correlates of facial affect processing in children and adolescents with autism spectrum disorder. *J Am Acad Child Adolesc Psychiatry* 2004; 43(4):481-90.

Abstract: **OBJECTIVE:** To examine the neural basis of impairments in interpreting facial emotions in children and adolescents with autism spectrum disorders (ASD). **METHOD:** Twelve children and adolescents with ASD and 12 typically developing (TD) controls matched faces by emotion and assigned a label to facial expressions while undergoing functional magnetic resonance imaging. **RESULTS:** Both groups engaged similar neural networks during facial emotion processing, including activity in the fusiform gyrus (FG) and prefrontal cortex. However, between-group analyses in regions of interest revealed that when matching facial expressions, the ASD group showed significantly less activity than the TD group in the FG, but reliably greater activity in the precuneus. During the labeling of facial emotions, no between-group differences were observed at the behavioral or neural level. Furthermore, activity in the amygdala was moderated by task demands in the TD group but not in the ASD group. **CONCLUSIONS:** These findings

suggest that children and adolescents with ASD in part recruit different neural networks and rely on different strategies when processing facial emotions. High-functioning individuals with ASD may be relatively unimpaired in the cognitive assessment of basic emotions, yet still show differences in the automatic processing of facial expressions.

Wang CC, Pies CA. Family, maternal, and child health through photovoice. *Matern Child Health J* 2004; 8(2):95-102.

Abstract: **OBJECTIVE:** (1) To introduce photovoice, a participatory action research methodology, for use by MCH program managers to enhance community health assessments and program planning efforts, (2) to enable community people to use the photovoice methodology as a tool to record, reflect, and communicate their family, maternal, and child health assets and concerns, and (3) to educate community leaders about family, maternal, and child health issues from a grassroots perspective. **METHODS:** Photovoice is based upon the theoretical literature on education for critical consciousness, feminist theory, and community-based approaches to documentary photography. Picture This Photovoice project took place in Contra Costa, an economically and ethnically diverse county in the San Francisco Bay area. Sixty county residents of ages 13-50 participated in 3 sessions during which they received training from the local health department in the techniques and process of photovoice. Residents were provided with disposable cameras and were encouraged to take photographs reflecting their views on family, maternal, and child health assets and concerns in their community, and then participated in group discussions about their photographs. Community events were held to enable participants to educate MCH staff and community leaders. **RESULTS:** The photovoice project provided MCH staff with information to supplement existing quantitative perinatal data and contributed to an understanding of key MCH issues that participating community residents would like to see addressed. Participants' concerns centered on the need for safe places for children's recreation and for improvement in the broader community environment within county neighborhoods. Participants' definitions of family, maternal, and child health assets and concerns differed from those that MCH professionals may typically view as MCH issues (low birth weight, maternal mortality, teen pregnancy prevention), which helped MCH program staff to expand priorities and include residents' foremost concerns. **CONCLUSIONS:** MCH professionals can apply photovoice as an innovative participatory research methodology to engage community members in needs assessment, asset mapping, and program planning, and in reaching policy makers to advocate strategies promoting family, maternal, and child health as informed from a grassroots perspective.

Wang CC, Wang Y, Zhang K *et al.* Reproductive health indicators for China's rural areas. *Soc Sci Med* 2003; 57(2):217-25.

Abstract: We report community-based development of reproductive health indicators for China's rural areas. To generate these indicators, we sequenced two participatory techniques known as nominal group process and Delphi survey methodology. Nominal group process entailed grassroots reproductive health workers' generating indicators, followed by refinement and prioritization of these indicators through a consensus-building Delphi process among nationally and internationally known reproductive health experts. Major criteria for the indicators were practicality, feasibility, and measurability within China's rural areas. We explain the importance of establishing these indicators for application in rural China and other developing countries as a complement to the World Health Organization's reproductive health indicators for global monitoring; present the identified indicators; and describe lessons learned from field testing in low-, middle-, and high-income counties of China's countryside.

Wang CS, Chou P. Risk factors for low birth weight among first-time mothers in southern Taiwan. *J Formos Med Assoc* 2001; 100(3):168-72.

Abstract: **BACKGROUND AND PURPOSE:** Low birth weight (LBW) greatly affects infant development, the family, and health care financial systems. Nonetheless, the risk factors for LBW in Taiwan have not been investigated. The purpose of this study was to determine the risk factors for LBW in Kaohsiung County. **METHODS:** In this cross-sectional study, we recruited 1,147 first-time mothers, including all adolescent mothers (< 20 years old) who gave birth during the period from June 1994 through May 1995 and all adult mothers (> or = 20 years old) who gave birth in January and February 1995. The subjects were interviewed during home visits or by telephone by public health nurses in each township. Logistic regression analysis was used to identify the risk factors for LBW in adolescent and adult mothers. **RESULTS:** The prevalence of LBW in the study population was 6.2%, ranging from 7.6% in adolescent mothers to 4.9% in adult mothers. Univariate analysis showed that mothers who had low pregravid weight (< 45 kg), infrequent prenatal visits (< 10), anemia, low gestational weight gain (< 10 kg), or habits of alcohol consumption or cigarette smoking were more likely to give birth to LBW infants. In logistic regression analysis, after controlling for covariates, the significant risk factors for LBW were low gestational weight gain (< 10 kg) and low pregravid weight (< 45 kg) for adolescent mothers. Infrequent prenatal visits (< 10) was the only significant risk factor for adult mothers. **CONCLUSIONS:** In this study, the risk factors for LBW among adolescent and adult mothers were different. This suggests that programs for prevention of LBW should be tailored according to maternal age,

begin before conception, and continue with enhanced surveillance during prenatal visits.

Wang L. Determinants of child mortality in LDCs: empirical findings from demographic and health surveys. *Health Policy* 2003; 65(3):277-99. Abstract: Empirical studies on child mortality at the disaggregated level-by social-economic group or geographic location-are more informative for designing health polices. Using Demographic and Health Survey data from over 60 low-income countries, this study (1) presents global patterns of the level and inequality in child mortality and (2) investigates the determinants of child mortality, both at the national level and separately for urban and rural areas. The global patterns of health outcomes reveal two interesting observations. First, as child mortality declines, the gap in mortality between the poor and the better-off widens. Second, while child mortality in rural areas is substantially higher than in urban areas, the reduction in child mortality is much slower in rural areas where the poor are concentrated. This suggests that health interventions implemented in the past decade may not have been as effective as intended in reaching the poor. The analysis on mortality determination shows that at the national level access to electricity, incomes, vaccination in the first year of birth, and public health expenditure significantly reduce child mortality. The electricity effect is large and independent of the income effect. While in urban areas, access to electricity is the only significant mortality determinant, in rural areas, vaccination in the first year of birth is the only significant factor.

Wang LM, Huang YT, Chern CH *et al.* Tele-emergency medicine: the evaluation of Taipei Veterans General Hospital and Kinmen-Granite Hospital in Taiwan. *Zhonghua Yi Xue Za Zhi (Taipei)* 2001; 64(11):621-8. Abstract: BACKGROUND: The purpose of the project was to establish computer networks between selected hospitals through high-speed communication and high power computer processing to electronically exchange medical information and to conduct clinical examination and consultation. Quality medical services can thus be provided to patients in the remote rural areas such as villages and small towns in the mountains, on the coasts and islets away from Taiwan. It also intended to facilitate continuing education for doctors in those areas. This study evaluates telemedicine between Taipei-Veterans General Hospital and Kinmen-Granite Hospital. METHODS: Patients were chosen from 1996-7 to 1997-6. The evaluation criteria included consulting quality, satisfaction of the doctors, benefits for the patients, and the charge being rendered. RESULTS: The results of evaluation for telemedicine between Taipei-Veterans General Hospital (VGHTPE) and Kinmen-Granite hospital (GH) are as follows: 93.0% doctors used telemedicine to seek a second opinion. After teleconsultation, the ratio of the patients showing

cooperation was over 80%. Over 98% doctors thought telemedicine system helpful. The doctors in VGHTPE are more satisfied with the facility than local doctors in Kinmen. CONCLUSIONS: The clinical evaluation of the telemedicine showed positive results. It can be a useful tool to facilitate on-job training and education Tele-emergency medicine.

Wang NE, Gisondi MA, Golzari M, van der Vlugt TM, Tuuli M. Socioeconomic disparities are negatively associated with pediatric emergency department aftercare compliance. *Acad Emerg Med* 2003; 10(11):1278-84.

Abstract: OBJECTIVES: This study sought to identify demographic, socioeconomic, and clinical predictors of aftercare noncompliance by pediatric emergency department (ED) patients. METHODS: The authors conducted a prospective, observational study of pediatric patients presenting to a university teaching hospital ED from July 1, 2002, through August 31, 2002. Demographic and clinical information was obtained from guardians during the ED visit. Guardians were contacted after discharge to determine compliance with ED aftercare instructions. Subjects were excluded if they were admitted or if guardians were unavailable or unwilling to consent. Data were analyzed using multivariable logistic regression to identify predictors of noncompliance from a list of predetermined variables. RESULTS: Of the 409 patients enrolled in the study, 111 were prescribed medications and 364 were given specific follow-up instructions. Subtypes of the variable "insurance status" were significantly associated with medication noncompliance in multivariable regression analysis. "Insurance status" and "low-acuity discharge diagnoses" were significantly associated with follow-up noncompliance. CONCLUSIONS: Disparity in health insurance has been shown to be a predictor of poor aftercare compliance for pediatric ED patients within the patient population.

Wang Y, Ollendick TH. A cross-cultural and developmental analysis of self-esteem in Chinese and Western children. *Clin Child Fam Psychol Rev* 2001; 4(3):253-71.

Abstract: In this review, we examine the construct of self-esteem from a cross-cultural perspective in Chinese and Western children and adolescents. We also explore the role of childrearing practices in the development of self-esteem in these different cultures. In doing so, we first review the concepts of emic (i.e., variations in patterns of behavior within a given culture) and etic research (i.e., variations in common patterns of behavior or activities across cultures). Then, we invoke Berry's notions of "imposed-etic" and "derived-etic" approaches (J. Berry, 1989) in understanding crucial cross-cultural differences that are evident in the literature. We pose basic questions such as: (1) What does self-esteem "look" like in Chinese children? (2) How do childrearing practices in China

influence the development of self-esteem in children? And, (3) what are the limitations of cross-cultural research in understanding a phenomenon such as self-esteem? We suggest that self-esteem does not "mean" the same things across these collectivist and individualistic cultures. We conclude our discourse with specific recommendations for clinical theory, research, and practice.

Ward C. Migrant mothers and the role of social support when child rearing. *Contemp Nurse* 2003-2004; 16(1-2):74-82.

Abstract: To raise children in a new country without the support of family and community may prove problematic for some women. This study explored the possible impact of a lack supportive social network on mothering. A cross sectional design using both quantitative (questionnaire) and qualitative approaches (interview) was used to investigate the child rearing experience of migrant women from the United Kingdom (UK) (N = 154) currently living in Western Australia (WA); 40 women were selected for interview. Bowlby's (1969) mother-infant attachment theory provides the theoretical framework to investigate the perceived loss of attachment to the homeland, attachment figure, country, culture and family. The results indicated that migrant women with children missed the close support of family networks; and indicate that all migrant mothers, regardless of origin, require a social support network to survive.

Ward FR. Parents and professionals in the NICU: communication within the context of ethical decision making--an integrative review. *Neonatal Netw* 2005; 24(3):25-33.

Abstract: Communication between parents and professionals in the NICU is a necessary part of collaborative decision making in the provision of family-centered care. Decisions with ethical components, those regarding treatment plans or neonatal research enrollment, need to be made conjointly with parents and health care professionals. This article reviews the present state of knowledge of how parents' input can be facilitated in regard to decisions made about their children. Research studies involving decisions made with ethical components in the NICU since the advent of the Baby Doe regulations reveal parents' frustration with communication practices, their need for control of information, and the trust in their children's health care providers that is required to best facilitate their input into ethical decisions made about their children.

Warren AR, Nunez N, Keeney JM, Buck JA, Smith B. The believability of children and their interviewers' hearsay testimony: when less is more. *J Appl Psychol* 2002; 87(5):846-57.

Abstract: Hearsay testimony from children's interviewers is increasingly common in sexual abuse trials, but little is known about its effects on juries. In 2 studies, the authors examined college students' perceptions of 3 types of hearsay testimony (an actual interview with a child or an adult interviewer providing either the gist of what that child had said or a verbatim account of the interview). Interviewers were rated as more accurate and truthful than the children. The interview was rated as higher quality, and children's statements, including their false statements, were sometimes rated as more believable in the interviewer gist hearsay condition. Mock jurors reacted differently to various types of hearsay testimony, and interviewer gist testimony may favor a child's case.

Warren JI, Hurt S, Loper AB, Bale R, Friend R, Chauhan P. Psychiatric symptoms, history of victimization, and violent behavior among incarcerated female felons: an American perspective. *Int J Law Psychiatry* 2002; 25(2):129-49.

Warren K, Craciun G, Anderson-Butcher D. Everybody else is: Networks, power laws and peer contagion in the aggressive recess behavior of elementary school boys. *Nonlinear Dynamics Psychol Life Sci* 2005; 9(2):155-73.

Abstract: This paper develops a simple random network model of peer contagion in aggressive behavior among inner-city elementary school boys during recess periods. The model predicts a distribution of aggressive behaviors per recess period with a power law tail beginning at two aggressive behaviors and having a slope of approximately -1.5. Comparison of these values with values derived from observations of aggressive behaviors during recess at an inner-city elementary school provides empirical support for the model. These results suggest that fluctuations in aggressive behaviors during recess arise from the interactions between students, rather than from variations in the behavior of individual students. The results therefore support those interventions that aim to change the pattern of interaction between students.

Warren SL, Gunnar MR, Kagan J *et al.* Maternal panic disorder: infant temperament, neurophysiology, and parenting behaviors. *J Am Acad Child Adolesc Psychiatry* 2003; 42(7):814-25. Abstract: OBJECTIVE: To determine whether 4- and 14-month-old infants of mothers with panic disorder (PD) would be more likely to show differences in temperament, neurophysiology (salivary cortisol and sleep), and relationships with their mothers than controls. METHOD: Two cohorts were recruited: 4-month-old infants with PD mothers (n = 25) and 4-month-old controls (n = 24), and 14-month-old infants with PD mothers (n = 27) and 14-month-old controls (n = 18). Mothers completed diagnostic interviews and questionnaires concerning infant temperament, sleep, and parenting. Infant salivary cortisol samples and standard observational procedures to measure infant temperament, sleep, attachment, and parenting were also used. RESULTS: Infants with PD mothers did not show more high reactivity, behavioral inhibition, or ambivalent/resistant attachment but did demonstrate different neurophysiology (higher salivary cortisol and more disturbed sleep) than controls. PD mothers also displayed less sensitivity toward their infants and reported parenting behaviors concerning infant sleep and discipline that have been associated with child problems. CONCLUSIONS: While infants with PD mothers did not show early behavioral differences from controls, they did display neurophysiological divergences consistent with higher arousal/arousability. Such neurophysiological divergences (elevated salivary cortisol and disturbed sleep) might be important early indicators of risk. Helping PD mothers parent their more highly aroused/arousable infants could reduce the development of psychopathology.

Waruru AK, Nduati R, Tylleskar T. Audio computer-assisted self-interviewing (ACASI) may avert socially desirable responses about infant feeding in the context of HIV. *BMC Med Inform Decis Mak* 2005; 5:24. Abstract: BACKGROUND: Understanding infant feeding practices in the context of HIV and factors that put mothers at risk of HIV infection is an important step towards prevention of mother to child transmission of HIV (PMTCT). Face-to-face (FTF) interviewing may not be a suitable way of ascertaining this information because respondents may report what is socially desirable. Audio computer-assisted self-interviewing (ACASI) is thought to increase privacy, reporting of sensitive issues and to eliminate socially desirable responses. We compared ACASI with FTF interviewing and explored its feasibility, usability, and acceptability in a PMTCT program in Kenya. METHODS: A graphic user interface (GUI) was developed using Macromedia Authorware and questions and instructions recorded in local languages Kikuyu and Kiswahili. Eighty mothers enrolled in the PMTCT program were interviewed with each of the interviewing mode (ACASI and FTF) and responses obtained in FTF interviews and ACASI compared

using McNemar's chi2 for paired proportions. A paired Student's t-test was used to compare means of age, marital-time and parity when measuring interview mode effect and two-sample Student's t-test to compare means for samples stratified by education level - determined during the exit interview. A Chi-Square (chi2test) was used to compare ability to use ACASI by education level. RESULTS: Mean ages for intended time for breastfeeding as reported by ACASI were 11 months by ACASI and 19 months by FTF interviewing (p < 0.001). Introduction of complementary foods at <or=3 months was reported more frequently by respondents in ACASI compared to FTF interviews for 7 of 13 complementary food items commonly utilized in the study area (p < 0.05). More respondents reported use of unsuitable utensils for infant feeding in ACASI than in FTF interviewing (p = 0.001). In other sensitive questions, 7% more respondents reported unstable relationships with ACASI than when interviewed FTF (p = 0.039). Regardless of education level, respondents used ACASI similarly and majority (65%) preferred it to FTF interviewing mainly due to enhanced usability and privacy. Most respondents (79%) preferred ACASI to FTF for future interviewing. CONCLUSION: ACASI seems to improve quality of information by increasing response to sensitive questions, decreasing socially desirable responses, and by preventing null responses and was suitable for collecting data in a setting where formal education is low.

Wasterlain CG, Niquet J, Thompson KW *et al.* Seizure-induced neuronal death in the immature brain. *Prog Brain Res* 2002; 135:335-53. Abstract: The response of the developing brain to epileptic seizures and to status epilepticus is highly age-specific. Neonates with their low cerebral metabolic rate and fragmentary neuronal networks can tolerate relatively prolonged seizures without suffering massive cell death, but severe seizures in experimental animals inhibit brain growth, modify neuronal circuits, and can lead to behavioral deficits and to increases in neuronal excitability. Past infancy, the developing brain is characterized by high metabolic rate, exuberant neuronal and synaptic networks and overexpression of receptors and enzymes involved in excitotoxic

mechanisms. The outcome of seizures is highly model-dependent. Status epilepticus may produce massive neuronal death, behavioral deficits, synaptic reorganization and chronic epilepsy in some models, little damage in others. Long-term consequences are also highly age- and model-dependent. However, we now have some models which reliably lead to spontaneous seizures and chronic epilepsy in the vast majority of animals, demonstrating that seizure-induced epileptogenesis can occur in the developing brain. The mode cell death from status epilepticus is largely (but not exclusively) necrotic in adults, while the incidence of apoptosis increases at younger ages. Seizure-induced necrosis has many of the biochemical features of apoptosis, with early cytochrome release from mitochondria and caspase activation. We speculate that this form of necrosis is associated with seizure-induced energy failure.

Watanabe Y, Ando H, Seo T, Katsuno S, Marui Y, Horisawa M. Two-dimensional alterations of myenteric plexus in jejunoileal atresia. *J Pediatr Surg* 2001; 36(3):474-8. Abstract: PURPOSE: The purpose of this report is to investigate changes in the myenteric plexus associated with the dilated proximal segment of jejunoileal atresia (JA). Two-dimensional morphologic changes in the myenteric nerve plexuses were investigated using whole-mount preparation. METHODS: Proximal (P) and distal (D) intestinal segments from 7 cases with JA and control (C) segments from 5 postmortem neonates were investigated. The circumference of the jejunoileal segments was measured after fixation. Antibodies for protein gene product 9.5 and neurofilament protein were used in whole-mount preparation. The sizes of neural networks were calculated by measuring the longest circular distance in a neural network (x) and the longest longitudinal distance (y), and the width of the internodal strands (i) with a videomicroscope. RESULTS: Median circumference of the segments was 8.5 in P, 2.0 in D, and 2.0 cm in C. The neural networks in P were expanded longitudinally as well as circularly (x = 817.10 microm, y = 561.26, i = 31.04; median) while comparing them to those in D (x = 431.40 microm, y = 288.07, i = 26.05) or C (x = 285.03 microm, y = 372.20, i = 1113.57, i = 32.39). The nerve plexus was less expanded than the intestinal wall. CONCLUSIONS: Proximal intestinal segments showed a restructuring that resulted in mild hypoplasia of the enteric nerve plexuses in the proximal segments. The less expansion of the myenteric nerve plexus seen in the proximal bowel in infants with JA suggests a histologic basis for the efficacy of tapering or plication of the dilated bowel.

Waterston T. A general paediatrician's practice in children's rights. *Arch Dis Child* 2005; 90(2):178-81.

Waterston T. Inequity in child health as a global issue. *Pediatrics* 2003; 112(3 Part 2):739-41.

Abstract: Poverty, violence, lack of education, abuse and exploitation, and refugee status are among the primary determinants of the health of children worldwide. There are 1.3 billion people living on less than 1 US dollars per day. Half the world's population, 3 billion people, live on less than 1.30 US dollars per day. Of the 4.4 billion people who live in developing countries, 60% lack access to sanitation, 33% lack clean water, 20% have no health care, and 20% do not have enough dietary energy and protein.(1) The world's 225 richest people have a combined wealth equivalent to the annual income of the poorest 2.5 billion people, nearly half of the world's population.(1) This article describes a number of the social, political, and environmental factors impacting children in the developing (southern hemisphere) world and how these are affected by actions taken in the developed (northern hemisphere) world.

Watson MR. Barriers to achieving and maintaining the oral health of Hispanics: working with the community to develop a community-based oral health promotion program. *Compend Contin Educ Dent* 2002; 23(12 Suppl):33-5.

Watson MR, Horowitz AM, Garcia I, Canto MT. A community participatory oral health promotion program in an inner-city Latino community. *J Public Health Dent* 2001; 61(1):34-41. Abstract: OBJECTIVES: This paper reports the planning, implementation, process evaluation, and refinement of an oral health community participatory project in Mount Pleasant, an inner-city Latino neighborhood of Washington, DC. The main goal was to explore the feasibility of implementing such a project. METHODS: The PRECEDE-PROCEED model was used to guide the planning and process evaluation of this project, in conjunction with community organizational methods. A steering committee, which met periodically, was formed to assist in program planning, implementation, and evaluation. The needs assessment of the community identified extensive dental health problems among children and deficiencies in their parents' oral health knowledge, opinions, and practices. In response, culturally appropriate health education and promotion activities were planned and implemented in collaboration with local community organizations, volunteers, and local practitioners. Process evaluation was used to provide feedback into the refinement of the community approach, which included record keeping and an inventory approach to activities completed and resources used. The overall impact and usefulness of this program were assessed informally using an anonymous open-ended questionnaire directed to

members of the steering committee, and an outreach survey using a convenience sample at a local Latino health fair. **RESULTS:** The implementation of such a community participatory approach was feasible and useful for building upon existing local resources and addressing oral health concerns in a community not reached by traditional dental care and health promotion initiatives. Individuals in this community showed a substantial interest in oral health matters and participated in a variety of oral health prevention activities. The community approach adhered to community-based research principles.

Watson N, Milat AJ, Thomas M, Currie J. The feasibility and effectiveness of pram walking groups for postpartum women in western Sydney. *Health Promot J Austr* 2005; 16(2):93-9. **Abstract:** **ISSUE ADDRESSED:** Women with children under five are the least physically active population group. We provided postpartum women living in western Sydney with the opportunity to participate in weekly pram walking groups and evaluated the effect of the intervention on self-reported physical activity, mental health and social indicators. **METHODS:** Mothers living in the intervention area (Blacktown LGA) and control area (Holroyd and Parramatta LGAs) completed a baseline questionnaire. Women in the intervention community were invited to participate in a pram walking group starting in the next month. The control group (n = 60) were also invited to participate in a pram walking group starting six months later. A follow-up questionnaire was completed by all mothers. **RESULTS:** There was no significant increase in the proportion of mothers in the intervention or control groups engaging in adequate physical activity from baseline to follow-up. However, intervention mothers increased their sessions of vigorous exercise and control mothers increased the amount of time spent walking. There were no significant differences at baseline or follow-up between the intervention and control groups in frequency of social contact or size of social networks. Nor was there a significant difference in satisfaction with social contact at baseline between the two groups. However, at follow-up women in the intervention group were more satisfied with the quality of their social contacts than the controls. **CONCLUSIONS:** Providing organised, community-based pram walking was not sufficient to increase overall physical activity levels among this group of postpartum women. The results suggest that the friendships formed in the pram walking group boosted mothers' satisfaction with social contact and possibly their mental health.

Webb CP, Burleson JA, Ungemack JA. Treating juvenile offenders for marijuana problems. *Addiction* 2002; 97 Suppl 1:35-45. **Abstract:** **AIMS:** This study investigated the characteristics and substance abuse treatment experience of two differentially defined groups of juvenile offenders, those who were referred or otherwise involved with the legal system and those who reported recent criminal behavior. **DESIGN:** Six hundred adolescents from the Cannabis Youth Treatment (CYT) Project were classified by criminal justice system involvement and recent criminal behavior. Multivariate and repeated-measures techniques explored substance use frequency, substance use problems, psychological and social risk factors and treatment outcomes as functions of criminal status. **FINDINGS:** Adolescents reporting criminal justice system involvement were comparable to adolescents reporting no legal involvement. Adolescents reporting past crime presented with heavier substance use, more substance use problems and greater psychological and environmental risks. Criminally active adolescents had greater reductions in substance use frequency and substance use problems during the course of treatment. **CONCLUSION:** Juvenile offender status, whether defined by criminal justice system involvement or criminal behavior, does not seem to mitigate the potential for adolescents to benefit from manual-guided outpatient treatments.

Webb G. Improving the care of Canadian adults with congenital heart disease. *Can J Cardiol* 2005; 21(10):833-8. **Abstract:** Canadian children with congenital heart disease (CHD) have been well cared for in the past half-century. These childhood success stories have resulted in there now being approximately 100,000 Canadian adults with CHD. Few of these patients have been cured or have normal hearts, and most were left with problems that will need to be addressed later in life. Approximately 55,000 such patients need expert care because their conditions are so rare or complicated that cardiologists and other caregivers have not been trained to look after them. Moreover, these 55,000 Canadians face premature mortality, the need for further surgery or the prospect of major complications. They need expert care to optimize the quality of their lives and to help them to avoid premature death. There is no plan for the care of these patients. When they reached 18 years of age, they were moved into an adult care system that does not understand them, does not care about them and has not provided for their care. Provincial and federal Ministries of Health have not yet taken an interest in these patients. Canadian professionals have taken important steps in support of adults with CHD. They established the Canadian Adult Congenital Heart Network, and they developed a National Care Plan and management guidelines for

their care. They have also made important contributions to the scientific literature, advancing the care of these patients. Waiting lists are much too long for adult patients with CHD. There are serious local and regional obstacles to the care of these patients because there are no provincial or regional plans for their care. Cardiologists who treat adult patients with CHD cannot earn enough in a fee-for-service system. There are serious human resource problems in Canadian Adult Congenital Heart Network centres that need to be addressed. There also needs to be greater coordination and integration between the pediatric and adult systems that care for these patients. Adults with CHD desperately need the help of the Heart and Stroke Foundations, leaders in the Canadian health care community and, ultimately, the Ministries of Health to help them protect their health and access expert care when needed in a timely way. The promises offered to them as children must also be honoured in their adult years.

Weberling LC, Forgays DK, Crain-Thoreson C, Hyman I. Prenatal child abuse risk assessment: a preliminary validation study. *Child Welfare* 2003; 82(3):319-34. Abstract: Workers need an efficient prenatal screener that can identify mothers at greatest risk of child abuse. Existing risk assessment methods are often invasive and difficult to administer. This study assessed child abuse risk in a sample of 49 expectant mothers using the Brigid Collins Risk Screener (BCRS). At three months postpartum, high-risk mothers scored significantly lower on the quality of infants' physical, social, and emotional environments than moderate or low-risk mothers. BCRS appears to offer a noninvasive, efficient approach to assessing risk of child abuse.

Webster SD, Bowers LE, Mann RE, Marshall WL. Developing empathy in sexual offenders: the value of offence re-enactments. *Sex Abuse* 2005; 17(1):63-77. Abstract: This paper describes an evaluation of different uses of role-play to enhance victim-specific empathy in sexual offenders. Thirty-three men participated in a treatment program involving offence re-enactment as described by Pithers (1994) and Mann, Daniels, and Marshall (2002). A matched group of 33 men participated in a treatment program that was identical in all respects except that they did not complete offence re-enactments. Instead, they completed extra role-plays designed to enhance empathy for the short and long-term consequences for their victim(s). Results indicated that completing an

offence re-enactment led to slightly better ability to identify some types of negative consequences for abuse victims, and identify cognitive distortions about their offending and women per se. Rapists in particular seemed more likely to benefit from offence re-enactment. The non-reenactment group showed better understanding of lifestyle disruption effects for sexual abuse victims. The differences between the groups were not very marked, and the study only involved measures of cognitive empathy. Given the concerns about offence re-enactment expressed by Pithers (1997), this procedure should be used with caution and future investigations should test specifically for possible signs of damage caused by the procedure.

Webster SW, O'Toole R, O'Toole AW, Lucal B. Overreporting and underreporting of child abuse: teachers' use of professional discretion. *Child Abuse Negl* 2005; 29(11):1281-96. Abstract: OBJECTIVE: According to mandatory reporting laws for professionals, the relationship between initial recognition that a child may have been abused and the subsequent reporting of that suspected case of child abuse to the responsible agency would, at first glance, appear to be clear. However, this relationship has developed into one of the major social policy controversies of the recent past. Our major goal is to present research findings that address this social policy debate concerning the problems of underreporting and overreporting, focusing specifically on teachers. METHOD: A factorial survey design, that combines the advantages of the factorial experiment with those of surveys, was employed in a probability sample of teachers (N=480) who responded to vignettes in which case characteristics were systematically manipulated. Teachers responded with judgments about whether the vignette was child abuse and the likelihood that they would report this suspected case. Characteristics of the teachers and their work setting (school) were also measured. RESULTS: When comparing the teachers' recognition and reporting scores, we found that they gave the same score for 63% of the vignettes they judged, gave higher reporting than recognition scores (overreporting) for 4% of the vignettes, and gave higher recognition than reporting scores (underreporting) for 33% of the vignettes. Discrepancies between recognition and reporting (over and under reporting) were related to characteristics of the case, teacher, and school where the teacher was employed. CONCLUSIONS: Teachers in our Ohio sample evidence the use of professional discretion in making judgments about the recognition and reporting of child abuse and do not appear to make these judgments with equal certainty. Their use of discretion is more likely to result in underreporting than overreporting.

Webster-Stratton C, Reid MJ, Hammond M. Preventing conduct problems, promoting social competence: a parent and teacher training partnership in head start. *J*

Clin Child Psychol 2001; 30(3):283-302. Abstract: Studied the effectiveness of parent and teacher training as a selective prevention program for 272 Head Start mothers and their 4-year-old children and 61 Head Start teachers. Fourteen Head Start centers (34 classrooms) were randomly assigned to (a) an experimental condition in which parents, teachers, and family service workers participated in the prevention program (Incredible Years) or (b) a control condition consisting of the regular Head Start program. Assessments included teacher and parent reports of child behavior and independent observations at home and at school. Construct scores combining observational and report data were calculated for negative and positive parenting style, parent-teacher bonding, child conduct problems at home and at school, and teacher classroom management style. Following the 12-session weekly program, experimental mothers had significantly lower negative parenting and significantly higher positive parenting scores than control mothers. Parent-teacher bonding was significantly higher for experimental than for control mothers. Experimental children showed significantly fewer conduct problems at school than control children. Children of mothers who attended 6 or more intervention sessions showed significantly fewer conduct problems at home than control children. Children who were the "highest risk" at baseline (high rates of noncompliant and aggressive behavior) showed more clinically significant reductions in these behaviors than high-risk control children. After training, experimental teachers showed significantly better classroom management skills than control teachers. One year later the experimental effects were maintained for parents who attended more than 6 groups. The clinically significant reductions in behavior problems for the highest risk experimental children were also maintained. Implications of this prevention program as a strategy for reducing risk factors leading to delinquency by promoting social competence, school readiness, and reducing conduct problems are discussed.

Weegels ME, van Veen MP. Variation of consumer contact with household products: a preliminary investigation. Risk Anal 2001; 21(3):499-511. Abstract: Little information is available on product use by consumers, which severely hampers exposure estimation for consumer products. This article describes actual contact with several consumer products, specifically dishwashing detergents, cleaning products, and hair styling products. How and where products are handled, as well as the duration, frequency, and amount of use were studied by means of diaries, in-home observations, and measurements. This study addressed the question, "To what extent are frequency, duration, and amount of use associated?" Findings showed that there was a large intra- as well as interindividual variation in frequency, duration, and amount of use, with the interindividual variation being

considerably larger. At the same time, results showed that, for a given activity, users tended to follow their own routine. Few relations were found among frequency, duration, and amount of use. It was concluded that among persons, frequency, duration, and amount of product act in practice as independent parameters. Diaries appear to be quite suitable for gaining insight into frequently used products. Observations of usage, recorded on video, were indispensable for obtaining particular information on product use. In addition, home visits enabled the collection of specific measurements. Although diaries and home visits are time-consuming, the combination provided insight into variation as well as relations among frequency, duration, and amount of use.

Wei JS, Greer BT, Westermann F *et al.* Prediction of clinical outcome using gene expression profiling and artificial neural networks for patients with neuroblastoma. Cancer Res 2004; 64(19):6883-91. Abstract: Currently, patients with neuroblastoma are classified into risk groups (e.g., according to the Children's Oncology Group risk-stratification) to guide physicians in the choice of the most appropriate therapy. Despite this careful stratification, the survival rate for patients with high-risk neuroblastoma remains <30%, and it is not possible to predict which of these high-risk patients will survive or succumb to the disease. Therefore, we have performed gene expression profiling using cDNA microarrays containing 42,578 clones and used artificial neural networks to develop an accurate predictor of survival for each individual patient with neuroblastoma. Using principal component analysis we found that neuroblastoma tumors exhibited inherent prognostic specific gene expression profiles. Subsequent artificial neural network-based prognosis prediction using expression levels of all 37,920 good-quality clones achieved 88% accuracy. Moreover, using an artificial neural network-based gene minimization strategy in a separate analysis we identified 19 genes, including 2 prognostic markers reported previously, MYCN and CD44, which correctly predicted outcome for 98% of these patients. In addition, these 19 predictor genes were able to additionally partition Children's Oncology Group-stratified high-risk patients into two subgroups according to their survival status ( $P = 0.0005$ ). Our findings provide evidence of a gene expression signature that can predict prognosis independent of currently known risk factors and could assist physicians in the individual management of patients with high-risk neuroblastoma.

Weigl DM, Bar-On E, Katz K. Small-fragment wounds from explosive devices: need for and timing of fragment removal. J Pediatr Orthop 2005; 25(2):158-61. Abstract: The management of soft tissue small-fragment wounds caused by bombs remains controversial. The authors analyzed the outcome of low-energy foreign body injuries in 10 pediatric

victims of suicide bomber attacks treated in their institution over a 2-year period. Two died during primary surgery. The eight survivors underwent a total of 10 procedures for removal of foreign bodies. Average follow-up was 24.1 months. The indications for the procedures were analyzed by the time of their performance: immediate, as part of the primary emergency operation (n = 2); intermediate, within 2 weeks after injury (n = 3); and late, more than 2 weeks after injury (n = 5). The results showed that all operations performed for objective indications were done within the immediate or intermediate period, whereas those done for subjective reasons were all but one performed in the late period. By the final follow-up visit, all foreign bodies had been removed. In conclusion, fragment removal is best done during the primary procedure if it does not pose a significant risk of complications.

Weigle CG, Markovitz BP, Pon S. The Internet, the electronic medical record, the pediatric intensive care unit, and everything. *Crit Care Med* 2001; 29(8 Suppl):N166-76.

Abstract: This article details how computers have changed life for those of us in pediatric intensive care. A week of clinical activity is described, with a focus on the interactions with computer systems that have become an integral part of patient-care activities for many of us. It becomes clear that the boundaries between personal computers, hospital systems, and the Internet are often not sharply defined. Resources that are used every week may include those residing on a personal digital assistant, on the hospital's electronic medical record, or on a distant site on the World Wide Web. Key resources on the Internet (World Wide Web and e-mail) are identified. The technical underpinnings, particularly the network that provides the infrastructure for various resources, are described.

Weil WB. Russian roulette: final 2. *Pediatrics* 2005; 115(5):1451.

Weinberger LE, Sreenivasan S, Sathyavagiswaran L, Markowitz E. Child and adolescent suicide in a large, urban area: psychological, demographic, and situational factors. *J Forensic Sci* 2001; 46(4):902-7. Abstract: We examined all completed suicides by children and adolescents in Los Angeles County who died during 1996 and 1997. There were 46 subjects, aged 11 through 16. The majority of the decedents were males and over age 14. The predominant racial group was Hispanic. There was an almost even split between firearms and hanging as the means of death. Females had a statistically significantly higher rate of prior suicide attempts than males. Over one-third left a suicide note, almost one-half were noted to be depressed, and 22% tested positive for alcohol or illicit drugs. Less than one-quarter were in mental health treatment. Eighty-seven percent had difficulty

transitioning to or during adolescence; e.g., problems at home, legal and school difficulties, and relationship losses. These findings are discussed in terms of Eriksonian developmental theory. We offer recommendations for intervention and prevention of suicide.

Weine S, Muzurovic N, Kulauzovic Y *et al.* Family consequences of refugee trauma. *Fam Process* 2004; 43(2):147-60.

Abstract: OBJECTIVE: To construct a model on the consequences of political violence for refugee families based upon a qualitative investigation. METHODS: This study used a grounded-theory approach to analyze qualitative evidence from the CAFES multi-family support and education groups with Bosnian refugee families in Chicago. Textual coding and analysis was conducted using ATLAS/ti for Windows. RESULTS: A grounded-theory model of Family Consequences of Refugee Trauma (FAMCORT) was constructed that describes Displaced Families of War across four realms of family life: (1) changes in family roles and obligations, (2) changes in family memories and communications, (3) changes in family relationships with other family members; and (4) changes in family connections with the ethnic community and nation state. In each realm, the model also specifies family strategies, called Families Rebuilding Lives, for managing those consequences. CONCLUSIONS: Political violence leads to changes in multiple dimensions of family life and also to strategies for managing those changes. Qualitative family research is useful in better understanding refugee families and in helping them through family-oriented mental health services.

Weingarten K. Witnessing the effects of political violence in families: mechanisms of intergenerational transmission and clinical interventions. *J Marital Fam Ther* 2004; 30(1):45-59.

Abstract: In this era of globalization, when news about political violence can haunt anyone, anywhere, those whose families have suffered political violence in the past are particularly vulnerable to current distress. Skilled in understanding transgenerational processes, family therapists need to be familiar with the mechanisms by which children are exposed to the effects of political violence suffered by their elders—that is, the ways in which they become their witnesses. This article presents a framework for understanding how the trauma of political violence experienced in one generation can "pass" to another that did not directly experience it, and proposes a model to guide clinical intervention.

Weis SE, Moonan PK, Pogoda JM *et al.* Tuberculosis in the foreign-born population of Tarrant county, Texas by immigration status. *Am J Respir Crit Care Med* 2001; 164(6):953-7.

Abstract: The epidemiology of tuberculosis is changing in the United States as a result of immigration, yet the extent to which different classes of immigrants contribute to overall morbidity is unknown. Tuberculosis in nonimmigrant visitors is of particular interest as they are currently exempt from screening requirements. We conducted a prospective survey of all culture-positive tuberculosis patients in Tarrant County, Texas from 1/98 to 12/00. Immigration status of foreign-born patients was classified as permanent residents, undocumented, or nonimmigrant visitors. Of 274 eligible participants, 114 (42%) were foreign-born; of these, 67 (59%) were permanent residents, 28 (25%) were undocumented, and 19 (17%) were nonimmigrant visitors. Among the foreign-born, we observed significant differences by immigration status in multidrug resistance ( $p = 0.02$ ), human immunodeficiency virus (HIV) infection ( $p = 0.0007$ ), and hospitalization ( $p = 0.03$  for ever/never, 0.01 for duration). Compared with other immigrants, more nonimmigrant visitors were multi-drug-resistant (16 % versus 11% of undocumented residents and 1% of permanent residents), were HIV-positive (32% versus 0% of undocumented and 5% of permanent residents), were hospitalized (47% versus 36% of undocumented and 19% of permanent residents), and had lengthy hospitalizations (median [midspread] days = 87 [25 to 153] versus 8.5 [4 to 28] for undocumented and 10 [7 to 24 d] for permanent residents). We found nonimmigrant visitors to be an important source of tuberculosis morbidity in Tarrant County. Further studies in other regions of the U.S. are needed to determine if screening and treatment recommendations of persons who spend extended periods in the U.S. should be raised to the standards set for permanent residents.

Weiss B. Ethics assessment as an adjunct to risk assessment in the evaluation of developmental neurotoxicants. *Environ Health Perspect* 2001; 109 Suppl 6:905-8. Abstract: The conduct of experimental studies in humans is governed by a body of principles whose main precepts have evolved over the past few decades. Three of these provide the foundations for judging the ethical adequacy of such an experiment. One addresses the question of who receives the benefits of the research and who bears its burdens (justice). A second requires that the research maximize the potential benefits to the subjects and minimize the risk of harm (beneficence). The third, the source of guidelines for informed consent, requires that subjects enter into the research voluntarily and with adequate information (respect for persons). Unlike research conducted to evaluate drugs, however, environmental exposures to potentially toxic chemicals do not survey those exposed for their consent, nor do they provide an appropriate calculus for measuring risks and benefits, which typically involve two different populations. Especially for exposure to developmental neurotoxicants, where the risk-benefit incompatibility

can be so striking, another element may need to be incorporated into risk characterization: a process of ethics assessment. A scheme for doing so can be derived from the procedures of fuzzy logic, which allow rules to be formulated that are applicable to ethical principles. Such an approach incorporates some of the tenets of the precautionary principle.

Weiss HB, Little PM, Bouffard SM. More than just being there: balancing the participation equation. *New Dir Youth Dev* 2005; (105):15-31, 9-10. Abstract: The research and evaluation evidence is mounting: out-of-school-time (OST) programs can keep young people safe, support working families, and improve academic achievement and social development. Over 6 million children are enrolled in after-school programs nationwide, but an estimated 14.3 million children still care for themselves in the nonschool hours. Because of this discrepancy, OST stakeholders need information about how to maximize participation in OST programs. The Harvard Family Research Project (HFRP) has developed a conceptual model, based on scholarly theory, empirical research, and knowledge gained from providers, that describes the characteristics that predict participation in OST programs as well as the potential benefits of that participation. In the center of the model, participation is conceived as a three-part construct of enrollment, attendance, and engagement. This equation serves as the basis for framing this issue of *New Directions for Youth Development*. The chapter provides an overview of why participation in OST programs matters for young people, describes some of the barriers and challenges to youth participation, teases out more precise definitions of participation, and presents HFRP's conceptual model of participation. It focuses on the participation equation and concludes by highlighting some overarching themes that recur throughout the issue and that have an impact on future directions for research and evaluation.

Weiss K. Authority as coercion: when authority figures abuse their positions to perpetrate child sexual abuse. *J Child Sex Abus* 2002; 11(1):27-51. Abstract: ABSTRACT. This article discusses child sexual abuse by a person in a position of authority, such as the child's teacher, guardian, relative, sports coach, or other person with authority over a child because of his/her particular position. The article tracks the recent trend toward recognizing position of authority in both state legislation and judicial precedent. Understanding the confusion and intimidation surrounding a child's experiences as a result of being sexually abused by a person in a position of authority often explains why children often fail to report or delay in reporting such abuse. Thus, existence of a perpetrator's position of authority in a particular case of child sexual abuse should influence a court's rulings on the elements of sexual abuse or assault in particular state statutes, as well as what

evidence should be admissible. Ultimately, the author concludes that all states should recognize position of authority in their child abuse statutes, that such statutes should be interpreted broadly by the courts, and, finally, that evidence of the defendant's prior acts of sexual abuse should almost always be admissible at trial.

Weissenberger AA, Dell ML, Liow K *et al.* Aggression and psychiatric comorbidity in children with hypothalamic hamartomas and their unaffected siblings. *J Am Acad Child Adolesc Psychiatry* 2001; 40(6):696-703. Abstract: OBJECTIVE: To assess aggression and psychiatric comorbidity in a sample of children with hypothalamic hamartomas and gelastic seizures and to assess psychiatric diagnoses in siblings of study subjects. METHOD: Children with a clinical history of gelastic seizures and hypothalamic hamartomas (n = 12; age range 3-14 years) had diagnoses confirmed by video-EEG and head magnetic resonance imaging. Structured interviews were administered, including the Diagnostic Interview for Children and Adolescents-Revised Parent Form (DICA-R-P), the Test of Broad Cognitive Abilities, and the Vitiello Aggression Scale. Parents were interviewed with the DICA-R-P about each subject and a sibling closest in age without seizures and hypothalamic hamartomas. Patients were seen from 1998 to 2000. RESULTS: Children with gelastic seizures and hypothalamic hamartomas displayed a statistically significant increase in comorbid psychiatric conditions, including oppositional defiant disorder (83.3%) and attention-deficit/hyperactivity disorder (75%). They also exhibited high rates of conduct disorder (33.3%), speech retardation/learning impairment (33.3%), and anxiety and mood disorders (16.7%). Significant rates of aggression were noted, with 58% of the seizure patients meeting criteria for the affective subtype of aggression and 30.5% having the predatory aggression subtype. Affective aggression was significantly more common ( $p < .05$ ). Unaffected siblings demonstrated low rates of psychiatric pathology on semistructured parental interview and no aggression as measured by the Vitiello Aggression Scale. CONCLUSIONS: Children with hypothalamic hamartomas and gelastic seizures had high rates of psychiatric comorbidity and aggression. Parents reported that healthy siblings had very low rates of psychiatric pathology and aggression.

Weitzman CC, Roy L, Walls T, Tomlin R. More evidence for reach out and read: a home-based study. *Pediatrics* 2004; 113(5):1248-53. Abstract: OBJECTIVE: Reach Out and Read (ROR), a clinic-based literacy program, has been shown to improve literacy outcomes in impoverished children. No study has used direct observation to assess a child's home literacy environment or to control for important confounders, such as the quality of the home environment. The objective of this study was to determine the relationship between the frequency of

ROR encounters that a family receives during well-child visits and a child's home literacy profile, while accounting for important confounders, such as the quality of the home environment. METHODS: A cross-sectional study was conducted of 137 children (aged 18-30 months) who received pediatric well-child care at the Yale-New Haven Hospital Primary Care Center. The number of ROR encounters that the family received was determined through parent interview, direct observation, and a review of the medical record. After a brief waiting room interview, a home visit was conducted. An assessment of the child's home literacy environment was completed on the basis of 10 variables that were obtained from parent report and direct observation within the home. These variables were summed to form a Child Home Literacy Index. The Home Observation for Measurement of the Environment, a standardized measure of the nurturing quality of the home environment, was also administered. Hierarchical linear regression was conducted to determine the significance of ROR on a child's home literacy environment. RESULTS: A total of 100 families completed both a waiting room interview and a home visit. Families received between 0 and 6 books in the ROR program. A total of 93% of families reported reading to their children, but only 35% of parents identified reading as a favorite activity of their child and 45% of parents reported that this was a favorite joint activity. Hierarchical linear regression demonstrated that increasing frequency of ROR encounters contributed a small but significant portion of the variance explaining a child's home literacy profile (5%), with this model accounting for a total of 19% of the variance. CONCLUSIONS: A modest literacy intervention, such as ROR, can have a significant impact on a child's home literacy environment.

Welles-Nystrom B. Co-sleeping as a window into Swedish culture: considerations of gender and health care. *Scand J Caring Sci* 2005; 19(4):354-60. Abstract: The purpose of this study is to examine the Swedish practice of co-sleeping and relate it to the cultural discourse on the gendered family and health. The Swedish study, part of the International Study of Parents, Children and Schools, focuses on some Western parents' ideas about health, child development, child-rearing goals and parental practices. It also addressed specific questions regarding parents' theories about the nature, gender and frequency of co-sleeping in Swedish families. Quantitative and qualitative data were collected with five cohorts of parents and their 60 children who ranged in age from 6 months to 8 years. The sample was balanced for sex and birth order. Parents completed batteries of standardized questionnaires and they were interviewed about their beliefs and practices related to child rearing and child development. A questionnaire about co-sleeping was sent post hoc to the families. The results showed that Swedish children often co-sleep with both their parents

until school age, when more boys than girls cease the practice. This is an important finding, because much of the literature suggests that this practice exists primarily for infants in non-Western cultures who co-sleep with their mothers. Co-sleeping in Sweden is perceived as a normal family activity, which differed from the other societies studied. Thus, the study of practice has important methodological implications. When a family practice is studied, carefully documented and understood in its many dimensions, it provides a window into the culture in which the practice is embedded and may explain how gender relates to the practice. For health-care professionals who encounter families from diverse cultural backgrounds, this methodological approach illustrates how parenting practices relate to health-care issues.

Welsh JP, Ahn ES, Placantonakis DG. Is autism due to brain desynchronization? *Int J Dev Neurosci* 2005; 23(2-3):253-63.

Abstract: The hypothesis is presented that a disruption in brain synchronization contributes to autism by destroying the coherence of brain rhythms and slowing overall cognitive processing speed. Particular focus is on the inferior olive, a precerebellar structure that is reliably disrupted in autism and which normally generates a coherent 5-13 Hz rhythmic output. New electrophysiological data reveal that the continuity of the rhythmical oscillation in membrane potential generated by inferior olive neurons requires the formation of neuronal assemblies by the connexin36 protein that mediates electrical synapses and promotes neuronal synchrony. An experiment with classical eyeblink conditioning is presented to demonstrate that the inferior olive is necessary to learn about sequences of stimuli presented at intervals in the range of 250-500 ms, but not at 700 ms, revealing that a disruption of the inferior olive slows stimulus processing speed on the time scale that is lost in autistic children. A model is presented in which the voltage oscillation generated by populations of electrically synchronized inferior olivary neurons permits the utilization of sequences of stimuli given at, or faster than, 2 per second. It is expected that the disturbance in inferior olive structure in autism disrupts the ability of inferior olive neurons to become electrically synchronized and to generate coherent rhythmic output, thereby impairing the ability to use rapid sequences of cues for the development of normal language skill. Future directions to test the hypothesis are presented.

Werber D, Dreesman J, Feil F *et al.* International outbreak of Salmonella Oranienburg due to German chocolate. *BMC Infect Dis* 2005; 5(1):7. Abstract: BACKGROUND: This report describes a large international chocolate-associated Salmonella outbreak originating from Germany. METHODS: We conducted epidemiologic investigations including a case-control study, and food safety investigations. Salmonella (S.) Oranienburg isolates were subtyped by

the use of pulsed-field gel electrophoresis (PFGE). RESULTS: From 1 October 2001 through 24 March 2002, an estimated excess of 439 S. Oranienburg notifications was registered in Germany. Simultaneously, an increase in S. Oranienburg infections was noted in other European countries in the Enter-net surveillance network. In a multistate matched case-control study in Germany, daily consumption of chocolate (matched odds ratio [MOR]: 4.8; 95% confidence interval [CI]: 1.3-26.5), having shopped at a large chain of discount grocery stores (MOR: 4.2; CI: 1.2-23.0), and consumption of chocolate purchased there (MOR: 5.0; CI: 1.1-47.0) were associated with illness. Subsequently, two brands from the same company, one exclusively produced for that chain, tested positive for S. Oranienburg. In two other European countries and in Canada chocolate from company A was ascertained that also contained S. Oranienburg. Isolates from humans and from chocolates had indistinguishable PFGE profiles. No source or point of contamination was identified. Epidemiological identification of chocolate as a vehicle of infections required two months, and was facilitated by proxy measures. CONCLUSIONS: Despite the use of improved production technologies, the chocolate industry continues to carry a small risk of manufacturing Salmonella-containing products. Particularly in diffuse outbreak-settings, clear associations with surrogates of exposure should suffice to trigger public health action. Networks such as Enter-net have become invaluable for facilitating rapid and appropriate management of international outbreaks.

Werneck GL, Rodrigues L, Santos MV *et al.* The burden of Leishmania chagasi infection during an urban outbreak of visceral leishmaniasis in Brazil. *Acta Trop* 2002; 83(1):13-8.

Abstract: First noted in the city of Teresina in 1981, the last decades have witnessed a remarkable increase in urban transmission of American visceral leishmaniasis (VL) in many Brazilian cities. Teresina, the site of this study, has faced two large outbreaks of VL. The first occurred from 1981-1985 when almost 1000 new cases were reported. The second started in the 1990s, and between 1993 and 1996 more than 1200 new cases were detected. This report describes the prevalence of infection with Leishmania chagasi in Teresina at the end of the second outbreak and gives estimates of the number of people who became infected during the epidemic. Between June 1995 and May 1996, 200 households were chosen at random from a list of addresses covering about 93% of Teresina's urban households. In each household, one person over the age of 1 year was screened for Leishmania antibodies and skin-tested. Nearly 50% of persons had a positive leishmanin reaction, but only 13.9% had detectable antibodies to L. chagasi. While prevalence estimates based on the leishmanin skin-test increased with age ( $P < 0.001$ ), those based on serological tests showed a lesser, and non significant, variation with age ( $P = 0.31$ ).

Using a geometric growth equation, and assuming that the annual distribution of clinical cases may serve as an approximation to what would have been the distribution of infections by year, we estimated that over 320000 persons were infected during the epidemic. Little is known about the epidemiology of VL in urban areas, where social networks, population density, and relationships of housing with the natural environment are more varied and complex than in the rural scene. In those areas, control interventions have failed to eliminate transmission of the parasite and prevent new epidemics. Further epidemiological studies of VL in urban areas might be needed to inform control actions.

Werner MJ. Principles of child health care financing. American Academy of Pediatrics Committee on Child Health Financing. *Pediatrics* 2003; 112(4):997-9. Notes: CORPORATE NAME: American Academy of Pediatrics Committee on Child Health Financing Abstract: Child health care financing must maximize access to quality, comprehensive pediatric and prenatal health care. This policy statement replaces the 1998 policy statement by the same title. Changes reflect recent state and federal legislation that affect child health care financing. The principles outlined in the statement will be used to evaluate the changing structure of child health care financing.

West JC. Hospital may be liable for actions of nurse who molested child. *E.P. v. McFadden*,-- So. 2d, 2000 WL 303063, No. 298 (Ct. Civ. App. Ala. March 24, 2000). *J Healthc Risk Manag* 2001; 21(2):46-7.

Westermann G, Reck Miranda E. A new model of sensorimotor coupling in the development of speech. *Brain Lang* 2004; 89(2):393-400. Abstract: We present a computational model that learns a coupling between motor parameters and their sensory consequences in vocal production during a babbling phase. Based on the coupling, preferred motor parameters and prototypically perceived sounds develop concurrently. Exposure to an ambient language modifies perception to coincide with the sounds from the language. The model develops motor mirror neurons that are active when an external sound is perceived. An extension to visual mirror neurons for oral gestures is suggested.

Wexler ID, Branski D, Kerem E. Treatment of sick children during low-intensity conflict. *Lancet* 2005;

Whaley SE, O'Connor And MJ, Gunderson B. Comparison of the adaptive functioning of children prenatally exposed to alcohol to a nonexposed clinical sample. *Alcohol Clin Exp Res* 2001; 25(7):1018-24. Abstract: BACKGROUND: Several studies show impairments in the social and adaptive behaviors of children prenatally exposed to alcohol. However, there remains limited consensus on whether the alcohol exposure directly affects social functioning or whether its effect is mediated by deficits in IQ. In addition, no studies have investigated whether deficits in social functioning are significantly more pronounced in children prenatally exposed to alcohol than in children referred to psychiatric treatment who were not prenatally exposed. We explored the effect of alcohol exposure on social and adaptive functioning and explored whether or not social and adaptive functioning are significantly more impaired in children prenatally exposed to alcohol than in a clinical sample of children. METHODS: A sample of 33 alcohol-exposed children was compared with a sample of 33 clinic-referred nonexposed children. The groups were compared on measures of communication, daily living skills, and socialization. The groups were matched on sex, age, IQ, and outpatient or inpatient status. RESULTS: Analyses revealed that the prenatally alcohol-exposed children did not differ significantly from the nonexposed children in any of the domains of adaptive functioning. However, with age, exposed children showed a more rapid decline in socialization standard scores compared with the nonexposed clinical sample. CONCLUSIONS: Young children who were exposed to alcohol prenatally show deficits in all domains of adaptive functioning. Although these deficits do not seem to differ from those exhibited by young children with psychiatric problems but no prenatal exposure, deficits in socialization behavior of prenatally exposed children may become more significant with age.

While A. Awful things can happen inside the home. *Br J Community Nurs* 2001; 6(7):369.

Whitbeck LB, Hoyt DR, McMorris BJ, Chen X, Stubben JD. Perceived discrimination and early substance abuse among American Indian children. *J Health Soc Behav* 2001; 42(4):405-24. Abstract: This study investigated internalizing and externalizing symptoms as potential mediators of the relationship between perceived discrimination and early substance abuse among 195 American Indian 5 through 8 graders from three reservations that share a common culture (e.g., language, spiritual beliefs, and traditional practices) in the upper Midwest. The

findings indicated that, although perceived discrimination contributed significantly to internalizing symptoms among the adolescents, internalizing symptoms were unrelated to early substance abuse. Rather, the effects of perceived discrimination on early substance abuse were mediated by adolescent anger and delinquent behaviors. The results are discussed in terms of the consequences of perceived discrimination on the development of American Indian early adolescents.

White HR, Chen PH. Problem drinking and intimate partner violence. *J Stud Alcohol* 2002; 63(2):205-14. Abstract: OBJECTIVE: This study examined the role of problem drinking in intimate partner violence (IPV) perpetration and victimization for men and women. We assessed (1) whether the relationship between problem drinking and IPV was spurious and (2) if relationship dissatisfaction and partner drinking mediated the effects of problem drinking on IPV. METHOD: Five waves of longitudinal data from a nonclinical sample (N = 725; 400 women), aged 12 through 31 years, were analyzed to determine the effects of problem drinking on IPV after controlling for eight common risk factors. Regression analyses were conducted to determine whether relationship dissatisfaction and partner drinking patterns mediated the effects of problem drinking on IPV after controlling for these same risk factors. RESULTS: With controls, problem drinking significantly predicted perpetration and victimization for men and women. Partner drinking was not related to perpetration or victimization for men. For women, partner drinking was strongly related to perpetration and victimization. It fully mediated the effects of problem drinking on perpetration, but did not mediate these effects on victimization. Relationship dissatisfaction fully mediated the effects of problem drinking on male and female perpetration and partially mediated the effects on male victimization. Relationship dissatisfaction did not mediate the effects of problem drinking on female victimization. CONCLUSIONS: The relationship between problem drinking and IPV was not spurious for men or women. Heavier drinking by partners put women at greater risk for perpetration and victimization and mediated the effects of their own problem drinking on perpetration. Programs that prevent and treat problem drinking among young men should have a beneficial impact on reducing IPV.

White MA, Grilo CM. Ethnic differences in the prediction of eating and body image disturbances among female adolescent psychiatric inpatients. *Int J Eat Disord* 2005; 38(1):78-84. Abstract: OBJECTIVE: The current study examined predictors of eating and body image disturbances in psychiatrically hospitalized female adolescents and investigated whether the predictors differ by ethnicity. METHOD: Participants were 427 (320 Caucasian, 53 Latina, 54 African American) female adolescent

psychiatric inpatients. Predictors of eating disorder features (dietary restraint, binge eating, and purging) and body image dissatisfaction (BID) were tested separately for the three ethnic groups. In addition to the eating and BID variables, the following predictor variables were considered: depression, anxiety, impulsivity, negative self-esteem, peer insecurity, and abuse. RESULTS: Caucasians reported significantly higher levels of dietary restraint and BID than Latinas and African Americans, whereas reports of binge eating did not differ by ethnicity. Regression analyses revealed that the predictor variables accounted for significant and substantial amounts of the variance in the four eating and body image domains. Different psychological and social variables predicted eating disorder symptoms and BID across ethnic groups. DISCUSSION: These findings suggest, for psychiatrically hospitalized adolescent females, that different patterns of factors may contribute to the maintenance of eating and body image disturbances across ethnic groups. Future research testing models of the etiology or maintenance of these disturbances needs to include ethnicity to ascertain whether the hypothesized components operate differently by ethnicity.

White SR, Henretig FM, Dukes RG. Medical management of vulnerable populations and co-morbid conditions of victims of bioterrorism. *Emerg Med Clin North Am* 2002; 20(2):365-92, xi. Abstract: Planning for the medical response to bioterrorism has primarily focused around the needs of the population as a whole. There has been little discussion pertaining to certain vulnerable groups such as children, pregnant women, or immunocompromised patients, yet they will likely comprise a significant subset of the exposed population. In addition, they will be at increased risk for morbidity and mortality following an attack. The emergency response to bioterrorism will be more complex as it relates to these vulnerable populations. Careful consideration of their special needs, some of which are presented in this article, may refine our efforts.

Whitelaw A, Thoresen M. Clinical trials of treatments after perinatal asphyxia. *Curr Opin Pediatr* 2002; 14(6):664-8. Abstract: Following critical hypoxia-ischemia during labor and delivery, there is a window of therapeutic opportunity during hypoxic-ischemic encephalopathy. Meta-analysis of three randomized trials of prophylactic barbiturate therapy for neonatal hypoxic-ischemic encephalopathy showed no significant effect on death or disability. One randomized trial of allopurinol showed short-term benefits but was too small to test death or disability. No adequate trials of dexamethasone, calcium channel blockers, or magnesium sulphate have yet been completed, but pilot studies in infants have shown the cardiovascular risks of magnesium sulphate and calcium channel blockers.

There is considerable evidence from animal studies that posthypoxic mild hypothermia reduces brain injury. One small randomized trial of mild hypothermia found no adverse effects but was too small to examine death or disability. One large randomized trial of selective head cooling has finished recruitment and a number of large trials of systemic mild hypothermia are ongoing. As time is critical with post-hypoxic interventions, the delay involved in obtaining informed parental consent for such trials might obscure a clinically important therapeutic effect.

Whitfield A. The conjoined twins. Transcript of the speeches given at the BAFS annual dinner on 28 February 2002. British Academy of Forensic Sciences. *Med Sci Law* 2002; 42(4):277-80.

Whitfield CL, Dube SR, Felitti VJ, Anda RF. Adverse childhood experiences and hallucinations. *Child Abuse Negl* 2005; 29(7):797-810.  
Abstract: OBJECTIVE: Little information is available about the contribution of multiple adverse childhood experiences (ACEs) to the likelihood of reporting hallucinations. We used data from the ACE study to assess this relationship. METHODS: We conducted a survey about childhood abuse and household dysfunction while growing up, with questions about health behaviors and outcomes in adulthood, which was completed by 17,337 adult HMO members in order to assess the independent relationship of 8 adverse childhood experiences and the total number of ACEs (ACE score) to experiencing hallucinations. We used logistic regression to assess the relationship of the ACE score to self-reported hallucinations. RESULTS: We found a statistically significant and graded relationship between histories of childhood trauma and histories of hallucinations that was independent of a history of substance abuse. Compared to persons with 0 ACEs, those with 7 or more ACEs had a five-fold increase in the risk of reporting hallucinations. CONCLUSION: These findings suggest that a history of childhood trauma should be looked for among persons with a history of hallucinations.

Whitty MT. Pushing the wrong buttons: men's and women's attitudes toward online and offline infidelity. *Cyberpsychol Behav* 2003; 6(6):569-79.  
Abstract: Despite current researchers' interest in the study of online sexual addiction, there is a dearth of research available on what constitutes online infidelity. This paper attempts to redress this balance by comparing 1,117 participants' attitudes toward online and offline acts of infidelity. A factor analysis was

carried out that yielded three components of infidelity: sexual infidelity, emotional infidelity, and pornography. More importantly, this study revealed that online acts of betrayal do not fall into a discrete category of their own. A MANOVA was performed and revealed a statistically significant difference on the combined dependent variables for the interaction of gender by age, age by relationship status, and Internet sexual experience. The hypotheses were, in part, supported. However, counter to what was predicted, in the main younger people were more likely to rate sexual acts as acts of betrayal than older individuals. It is concluded here that individuals do perceive some online interactions to be acts of betrayal. In contrast to some researchers' claims, it is suggested here that we do need to consider how bodies are reconstructed online. Moreover, these results have important implications for any treatment rationale for infidelity (both online and offline).

Wicks E. The greater good?: issues of proportionality and democracy in the doctrine of necessity as applied in *Re A*. *Common Law World Rev* 2003; 32(1):15-34.  
Notes: GENERAL NOTE: KIE: 70 fn.  
GENERAL NOTE: KIE: KIE Bib: patient care/minors  
Abstract: This article examines the criminal law doctrine of necessity as applied in the conjoined twins case (*Re A (Children) (Conjoined Twins: Surgical Separation)* [2000] 4 All ER 961). It determines that the public law principle of proportionality underlies the doctrine, but identifies the preservation of life as the guiding principle behind the Court of Appeal's use of necessity in *Re A*. The article is critical of this elevation of the preservation of life under the doctrine of necessity and argues for an alternative conception of necessity based upon fundamental constitutional principles such as human rights and democracy. The principle of democracy has particular pertinence to the issue of necessity because it may be endangered by this common law justificatory defence. This conflict between democracy and necessity, it is argued, further supports the need for the constitutional value of democracy to play a key role in any application of necessity in future cases.

Widom CS, Czaja SJ. Reactions to research participation in vulnerable subgroups. *Account Res* 2005; 12(2):115-38.

Notes: GENERAL NOTE: KIE: 27 refs.  
GENERAL NOTE: KIE: KIE Bib: behavioral research/special populations  
Abstract: This paper describes the extent to which vulnerable individuals (defined by economic, social, psychological, physical health, and child maltreatment status) react to research participation. As part of an ongoing longitudinal study, participants (N=896) completed a lengthy and intrusive in-person interview and provided a small amount of blood through finger pricks. At the end of the interview, participants were asked eight questions about their reactions to the

research experience. Vulnerable individuals in general agreed more strongly about having an emotional reaction, but were not less willing to continue to participate. In addition, psychologically vulnerable individuals more strongly agreed they would continue to participate, were treated with respect and dignity, and found their participation meaningful. Compared to whites, nonwhites reported stronger agreement about the meaningfulness of the research and the belief that their responses would be kept private. Like others, individuals vulnerable by virtue of their prisoner status or homelessness (past or current) agreed more strongly about having an emotional reaction to the interview, but otherwise did not differ in their reactions. These results suggest that researchers and institutional review boards should not be deterred from conducting research on sensitive topics with potentially vulnerable populations.

Wiehe VR. Empathy and narcissism in a sample of child abuse perpetrators and a comparison sample of foster parents. *Child Abuse Negl* 2003; 27(5):541-55. Abstract: OBJECTIVE: The purpose of this research was to study the personality variables of empathy and narcissism in a sample of child abuse perpetrators and a comparison sample of foster parents, conceptualized as nonabusive parents, in order to gain further understanding of perpetrators and to provide clues for intervention. METHOD: The sample consisted of two groups: physically and emotionally abusive parents (n=52) and foster parents (n=101). Participants responded to three instruments: the Interpersonal Reactivity Index (IRI), an instrument measuring individual differences in empathy, and two instruments measuring narcissism: the Narcissistic Personality Inventory (NPI) and the Hypersensitivity Narcissism Scale (HSNS). RESULTS: Statistically significant differences were found between the two groups on three of the four subscales of the IRI: perspective-taking, empathic concern, and personal distress. Based on the definition of these subscales, the abusive parents as compared to the foster parents were not able to take the perspective of another or see things from another's viewpoint, showed less warmth, compassion and concern for others, and experienced difficulty in tense interpersonal situations. Statistically significant differences were found for the two groups on three of the six subscales of the NPI: authority, exhibitionism, and superiority, and on the HSNS. The abusive parents demonstrated less self-confidence, a greater lack of impulse control and were more narcissistic than their foster parent counterparts. CONCLUSIONS: The results suggest that it is how the perpetrators experience aversive behavior in their children that may provoke them to physically and emotionally abuse their children. Their self-centeredness in addition to their deficiencies in empathy may cause them to experience their children's misbehavior as an affront to their authority. Implications for treatment are made from this conceptualization of parental abuse.

Wiener LS, Vasquez MJ, Battles HB. Brief report: fathering a child living with HIV/AIDS: psychosocial adjustment and parenting stress. *J Pediatr Psychol* 2001; 26(6):353-8.

Abstract: OBJECTIVE: To examine the psychosocial stressors experienced by fathers of children diagnosed with HIV/AIDS. METHODS: Thirty-one fathers whose children (ages 6 to 19) were participating in pediatric HIV clinical trials completed self-report measures of parenting stress, psychological distress, and need for psychosocial services. RESULTS: Over half of this sample experienced significantly elevated levels of both parenting stress and psychological distress compared to standardized norms. Ninety-seven percent of these men reported the need for services including gender-specific support groups, assistance with discipline, disease management, and assistance with planning for the future. CONCLUSIONS: Elevated levels of parenting stress and psychological distress in fathers of children living with HIV suggest the need for additional psychological intervention in this population.

Wierzbza TF, El-Yazeed RA, Savarino SJ *et al.* The interrelationship of malnutrition and diarrhea in a periurban area outside Alexandria, Egypt. *J Pediatr Gastroenterol Nutr* 2001; 32(2):189-96.

Abstract: BACKGROUND: In the developing world, children are often observed to have both diarrhea and malnutrition. This observation has led many researchers to speculate that diarrhea may produce malnutrition and that malnutrition may predispose to diarrhea. In this study, the interrelationship between diarrhea and malnutrition was investigated among 143 Egyptian children less than 3 years of age. METHODS: For 22 months, children were followed for diarrhea at twice weekly home visits and measured for nutritional status at approximately 3-month intervals. Nutritional measurements were converted to z-scores based on the National Center for Health Statistics/World Health Organization (NCHS/WHO) reference population. RESULTS: Three hundred fifty-eight diarrheal episodes were reported with only 1% of episodes lasting 14 days or more. Stunting, wasting, and low weight-for-age were found in 19%, 3%, and 7%, of these children, respectively. When testing whether malnutrition predisposes to diarrhea, a weight-for-age z-score of <-2 standard deviations was associated with increased incidence of diarrhea (RR = 1.7, P < 0.01) but not height-for-age or weight-for-height. Diarrhea itself was associated with a subsequent attack of diarrhea (RR = 2.1, P < 0.001). During short intervals of follow-up (approximately 3 months), an association was detected between diarrhea episodes and growth faltering for height-for-age z-score (-0.16, P < 0.05). This association was reduced, however, when analyzed during 6-month intervals, if no diarrhea was reported in either the first or second half of this interval. CONCLUSIONS: In a population with moderate malnutrition, both low weight-for-age and diarrhea

itself are associated with increased diarrhea risk. Diarrhea alone does not appear to contribute substantially to malnutrition when children have diarrhea-free time for catch-up growth.

Wiggins M, Oakley A, Roberts I *et al.* Postnatal support for mothers living in disadvantaged inner city areas: a randomised controlled trial. *J Epidemiol Community Health* 2005; 59(4):288-95.

Abstract: **STUDY OBJECTIVE:** To evaluate the effect of two forms of postnatal social support for disadvantaged inner city mothers on maternal and child health outcomes. **DESIGN:** Randomised controlled trial with economic and process evaluations and follow up at 12 and 18 months. The two intervention groups received either the offer of a year of monthly supportive listening home visits by a support health visitor (SHV), or a year of support from community groups providing drop in sessions, home visiting and/or telephone support (CGS). Each was compared with a control group that received standard health visitor services. **SETTING:** Two disadvantaged boroughs of London, United Kingdom. **PARTICIPANTS:** 731 women from culturally diverse backgrounds with infants. **MAIN RESULTS:** At 12 and 18 months, there was little impact for either intervention on the main outcomes: child injury (SHV: relative risk 0.99; 95% confidence intervals 0.68 to 1.45, CGS: 0.91; 0.61 to 1.36), maternal smoking (SHV: 0.86; 0.62 to 1.19, CGS: 0.97; 0.72 to 1.33) or maternal depression (SHV: 0.86; 0.62 to 1.19, CGS: 0.93; 0.69 to 1.27). SHV women had different patterns of health service use (with fewer taking their children to the GP) and had less anxious experiences of motherhood than control women. User satisfaction with the SHV intervention was high. Uptake of the CGS intervention was low: 19%, compared with 94% for the SHV intervention. **CONCLUSIONS:** There was no evidence of impact on the primary outcomes of either intervention among this culturally diverse population. The SHV intervention was associated with improvement in some of the secondary outcomes.

Wiggs L. Sleep problems in children with developmental disorders. *J R Soc Med* 2001; 94(4):177-9.

Wijma B, Gustafsson LE, Thapar-Bjorkert S, Swahnberg K. What is an error? *J Psychosom Obstet Gynaecol* 2005; 26(4):233-5.

Wijnhoven TM, de Onis M, Onyango AW *et al.* Assessment of gross motor development in the WHO Multicentre Growth Reference Study. *Food Nutr Bull* 2004; 25(1):S37-45.

Abstract: The objective of the Motor Development Study was to describe the acquisition of selected gross motor milestones among affluent children growing up in different cultural settings. This study was conducted in Ghana, India, Norway, Oman, and the United States

as part of the longitudinal component of the World Health Organization (WHO) Multicentre Growth Reference Study (MGRS). Infants were followed from the age of four months until they could walk independently. Six milestones that are fundamental to acquiring self-sufficient erect locomotion and are simple to evaluate were assessed: sitting without support, hands-and-knees crawling, standing with assistance, walking with assistance, standing alone, and walking alone. The information was collected by both the children's caregivers and trained MGRS fieldworkers. The caregivers assessed and recorded the dates when the milestones were achieved for the first time according to established criteria. Using standardized procedures, the fieldworkers independently assessed the motor performance of the children and checked parental recording at home visits. To ensure standardized data collection, the sites conducted regular standardization sessions. Data collection and data quality control took place simultaneously. Data verification and cleaning were performed until all queries had been satisfactorily resolved.

Wildeman S, Downie J. Genetic and metabolic screening of newborns: must health care providers seek explicit parental consent? *Health Law J* 2001; 9:61-111. Notes: GENERAL NOTE: KIE: 181 fn. GENERAL NOTE: KIE: KIE Bib: genetic screening; informed consent/minors; mass screening

Wilder J, Granlund M. Behaviour style and interaction between seven children with multiple disabilities and their caregivers. *Child Care Health Dev* 2003; 29(6):559-67.

Abstract: **INTRODUCTION:** Recent studies show that the existing interaction patterns of children with multiple disabilities should be taken into consideration when planning communication interventions. For children with disabilities, it is especially important that the partner in interaction is sensitive and well aware of the importance of a qualitatively successful interaction. Wilder (unpublished report) found that the behaviour style of 30 children with multiple disabilities was more related to the caregiver-perceived interaction than the communicative skills and functional abilities of the children. This study inductively explored the caregivers' perceptions of interaction within seven caregiver-child dyads. The research questions were: How do the caregivers perceive the interaction? How do the caregivers perceive the children's behaviour style to be related to the interaction with the caregivers? **METHOD:** The children were selected individually from the participants in Wilder (unpublished report) depending upon the responses the caregivers had given about the children's self-regulation and reactivity in the Carolina Record of Individual Behaviour questionnaire. The study was undertaken by means of home visits where the caregivers participated in an interview asking about

their strategies for interaction, how they perceived the roles of the children and their own roles in interaction, the caregivers' opinion of what an interaction constituted of and the caregivers' aims and aspiration for interaction. The data analysis was performed by meaning concentration and categorization through a pendulum between the parts and the entirety of the interviews. In this way, hermeneutics and thematic analysis were both being practised. RESULTS: The results of the interviews are presented as a model with categorizations as a network. The categorizations reflect the system of themes that permeate how the caregivers perceived interaction in the dyad. The themes are: sharing of experience, successful interaction, role of the child, role of the caregiver, interaction methods, obstacles and facilitators and aims and aspirations. DISCUSSION: The caregivers perceived their own role in interaction to be of a sensitive leading kind. The caregivers lead the interaction by using their knowledge about the children's usual way of interacting, the children's behaviour styles, functional abilities, the children's current mood and situation as well as the whole context. They monitored the interaction such that, throughout an interaction sequence, the caregivers always tried to optimize the interaction between the parties in the dyad. The behaviour style was a background factor that the caregivers had knowledge of and scanned in their everyday turn taking. Although there were differences in the children's behaviour styles, the caregivers discussed the same themes in the interviews. The behaviour style became a facilitator for the whole interaction, forced the interaction in certain directions and made the interaction more complete with turn taking of different kinds from both parties. The findings show that it is imperative to see caregivers as experts on their children and to make them assertive in this in relation to professionals. Furthermore, as a successful interaction can boost the development of children, it is essential to direct interventions to the everyday interaction in caregiver-child dyads.

Wilfond BS, Gollust SE. Policy issues for expanding newborn screening programs: the cystic fibrosis newborn screening experience in the United States. *J Pediatr* 2005; 146(5):668-74. Abstract: OBJECTIVE: To describe the screening approaches and implementation strategies for cystic fibrosis newborn screening in the 12 programs that were offered in 11 states in 2002. STUDY DESIGN: Telephone interviews conducted in the spring of 2003 with program representatives in the 11 states. Screening approaches were defined in four overlapping categories: state mandated screening, state-wide offering, hospital based screening, and screening with informed consent. RESULTS: Screening was state mandated in seven states but was routinely offered to most infants in nine states. The primary care provider or hospital determined if screening was done in three states (four programs). Informed consent was explicitly

documented in two states. In five programs, immunoreactive trypsinogen exclusively was used to identify at-risk infants. In seven programs, a second tier DNA test was also used, but these programs each had distinct strategies. In only two programs where DNA testing was performed and normal sweat tests indicated carrier status, were results routinely provided to parents "in person" at a CF center. CONCLUSION: The diversity of approaches for screening approaches and strategies has advantages for future policy decisions, provided that data about the clinical and psychosocial impact of screening from these programs are collected and disseminated. As additional states determine that the resources are available, programs can be designed with a more favorable benefit/risk balance as a result of the successes and challenges faced by other states.

Wilke DJ, Kamata A, Cash SJ. Modeling treatment motivation in substance-abusing women with children. *Child Abuse Negl* 2005; 29(11):1313-23. Abstract: OBJECTIVES: Children are often considered a primary motivator for women seeking substance abuse treatment. This study tested a model predicting treatment motivation in substance-abusing mothers. METHODS: This study was a secondary analysis of the Drug Abuse Treatment Outcome Study (DATOS). It used structural equation modeling to describe factors influencing motivation for treatment. DATOS is a national study of substance abusers entering treatment. Treatment was provided by a sampling of community-based programs, free-standing hospitals, hospital units, county-funded programs, modified therapeutic communities, and criminal justice programs. The subsample of women with children under the age of 18 for whom custody of children could be determined was selected (n=1371). The variables comprising each factor were based on self-report, and standardized scales measuring level of drug involvement, psychological functioning, children, and a desire to stop using drugs were used. RESULTS: Drug involvement was positively related to poorer psychological functioning, child custody issues, and the desire to stop using drugs. Child custody issues had a negative influence, while poorer psychological functioning and a desire to stop using drugs positively influenced treatment motivation. CONCLUSIONS: The negative influence that children have on treatment motivation may reflect the practical or emotional difficulties of having to leave children behind or in some instances having children placed in foster care. Specifically, losing custody of children, particularly with little expectation they will be reunified, may serve as a detriment to motivation. Popular beliefs hold that children serve as a primary source of a mother's

treatment motivation; however this study found the opposite was true. Children should not automatically be considered a primary source of motivation for participation in treatment.

Wilkes G. Abused child to nonabusive parent: resilience and conceptual change. *J Clin Psychol* 2002; 58(3):261-76. Abstract: Individuals who were abused as children and have spontaneously, without intervention, been able to change their cognitive and behavioral patterns such that they do not abuse their own children represent a heretofore untapped source of information and understanding about the processes of conceptual change and resilience. This pilot study investigates the nature of this conceptual change as an exemplar of resilience. Birth order, gender, locus of control, and coping behaviors emerged as areas needing further study. Additionally, the belief on the part of the abusing parents that abuse was not wrong needs further investigation as a possible precursor to this particular context for conceptual change.

Wilkinson DL, Kurtz EM, Lane P, Fein JA. The emergency department approach to violently injured patient care: a regional survey. *Inj Prev* 2005; 11(4):206-8. Abstract: OBJECTIVE: Since the early 1990s public health workers have challenged healthcare practitioners to take an active role in violence prevention with patients aged 10-24 years. Emergency department (ED) clinicians are uniquely positioned to identify, assess, and refer youth involved in violent events. The objective of this study was to describe ED directors' estimate of the number of violently injured youth seen, the presence of established protocols or guidelines for handling youth violence, and the type of training programs offered to ED physicians regarding this issue. METHODS: The authors conducted a survey of EDs (n = 64) in the Philadelphia metropolitan region to determine the standard of ED care for violently injured youths. Half of the EDs were in urban areas and half in suburban. RESULTS: A total of 41 out of 64 (64.1%) ED directors completed and returned the written questionnaire. In addition to treating the specific injuries sustained, ED responses to youth violence primarily involved talking with patients about the events surrounding the injury. The estimated number of violently injured youth seen per month varied considerably. Twenty four directors (58.5%) estimated that their institution treated fewer than 10 per month; 10 (24.4%) reported 11-30, and seven (17.1%) mostly large urban hospitals, saw more than 30 per month. Although most hospitals reported that the staff counsels patients about safety concerns, only 17% offered their staff formal training programs on youth violence. CONCLUSIONS: To address the prevention of youth violence, EDs need specific training programs for ED staff, as well as systematic risk assessment and referral resources for structured intervention and follow up.

Willgerodt MA, Kataoka-Yahiro M, Kim E, Ceria C. Issues of instrument translation in research on Asian immigrant populations. *J Prof Nurs* 2005; 21(4):231-9. Abstract: Health disparity research often includes non-English-speaking populations, and instrument translation is a major methodological issue with which researchers must contend. Yet most existing nursing research do not adequately describe translation method processes used. This article describes the procedures used to translate the Caregiver Reaction Assessment instrument into Ilocano for use in a study with elderly Filipinos caring for their grandchildren and the Parenting Practice Interview into Korean for use in a study of parenting practices among Korean immigrant parents. An explanation of Brislin's method for instrument translation is first provided, followed by a detailed description of how this method was applied in the two studies and the challenges encountered in assessing translation accuracy. Achieving semantic and content equivalence posed a major challenge in both studies. Recommendations for cross-cultural nursing research are provided; the experiences described in this article illuminate translation issues to be considered by nurse researchers.

Williams AC. Facial expression of pain: an evolutionary account. *Behav Brain Sci* 2002; 25(4):439-55; discussion 455-88. Abstract: This paper proposes that human expression of pain in the presence or absence of caregivers, and the detection of pain by observers, arises from evolved propensities. The function of pain is to demand attention and prioritise escape, recovery, and healing; where others can help achieve these goals, effective communication of pain is required. Evidence is reviewed of a distinct and specific facial expression of pain from infancy to old age, consistent across stimuli, and recognizable as pain by observers. Voluntary control over amplitude is incomplete, and observers can better detect pain that the individual attempts to suppress rather than amplify or simulate. In many clinical and experimental settings, the facial expression of pain is incorporated with verbal and nonverbal vocal activity, posture, and movement in an overall category of pain behaviour. This is assumed by clinicians to be under operant control of social contingencies such as sympathy, caregiving, and practical help; thus, strong facial expression is presumed to constitute and attempt to manipulate these contingencies by amplification of the normal expression. Operant formulations support skepticism about the presence or extent of pain, judgments of malingering, and sometimes the withholding of caregiving and help. To the extent that pain expression is influenced by environmental contingencies, however, "amplification" could equally plausibly constitute the release of suppression according to evolved contingent propensities that guide behaviour. Pain has been largely neglected in the evolutionary literature and the literature on expression of emotion, but an evolutionary account can generate

improved assessment of pain and reactions to it.

Williams CL, Grechanaia T, Romanova O, Komro KA, Perry CL, Farbakhs K. Russian-American partners for prevention. Adaptation of a school-based parent-child programme for alcohol use prevention. *Eur J Public Health* 2001; 11(3):314-21. Abstract: **BACKGROUND:** The Russian-American Partners for Prevention was an adaptation and evaluation of the Slick Tracy Home Team Program which was developed in Minnesota in order to delay the onset of drinking. The Slick Tracy Home Team Program was the first intervention of Project Northland, a large 3 year community trial of the efficacy of a public health intervention for under age drinking. **METHODS:** The programme was administered through schools, but involved parents using engaging and fun homework activities. The Russian version was implemented in fifth-grade classrooms in 20 Moscow schools with 1,212 students surveyed at baseline. Students were surveyed again after programme implementation (n = 1,182), of whom 980 were present at baseline. Parents of 1,078 students were surveyed by telephone after programme implementation. **RESULTS:** The results demonstrated the successful recruitment and retention of 20 Moscow schools in a research project, acceptability of programme materials in Russia, high participation rates, changes in students' knowledge about problems associated with under age drinking and some evidence about increases in parent-child communication about alcohol use. As in the USA, no changes in students' alcohol use rates were observed at the end of the first year of the 3 year programme. **CONCLUSION:** Russian youth, as compared to Americans, began drinking at earlier ages, received fewer prevention messages from their parents, and had fewer prevention programmes in school. The results suggested that carefully implemented and evaluated replications of the US Project Northland interventions might provide effective and appropriate school-based programmes for Russia.

Williams-Evans SA, Sheridan DJ. Exploring barriers to leaving violent intimate partner relationships. *ABNF J* 2004; 15(2):38-40. Abstract: This article discusses the barriers abused partners may have for not leaving the violent relationship. The authors discuss procedures they will use in testing two clinical screening tools: the HARASS tool and the Pitts-Williams Inquiry tool.

Williams J, Klinepeter K, Palmes G, Pulley A, Foy JM. Diagnosis and treatment of behavioral health disorders in pediatric practice. *Pediatrics* 2004; 114(3):601-6. Abstract: **OBJECTIVE:** There has been a strong push toward the recognition and treatment of children with behavioral health problems by primary care pediatricians. This study was designed to assess the

extent to which a sample of primary care pediatricians diagnose and treat behavioral health problems and to identify factors that may contribute to their behavioral health practice. **METHODS:** A standard interview was conducted with 47 pediatricians who work in primary care settings in a predominantly urban setting in North Carolina. Pediatricians' responses to questions about the estimated percentage of children in their practice with a behavioral health disorder, tools used to make diagnoses, frequent and infrequent diagnoses made, comfort level with making a diagnosis, reasons for not making a diagnosis, use of psychotropic medications, types of nonmedication interventions provided, educational background, and needs involving behavioral health issues were evaluated. **RESULTS:** Pediatricians estimated that the average percentage of children in their practices with a behavioral health disorder was 15%. The study did not find significant differences in perceptions related to time in practice or gender of the pediatric provider. The most frequent behavioral health diagnosis was attention-deficit/hyperactivity disorder (ADHD), and the majority incorporated behavioral questionnaires, expressed a high level of comfort with the diagnosis, and frequently or occasionally prescribed stimulants. Variability was noted in both practice and comfort for other behavioral health disorders. Slightly fewer than half of the pediatricians frequently diagnosed anxiety and depression. Those who make these diagnoses commonly incorporated questionnaires and reported frequent or occasional use of selective serotonin reuptake inhibitors. Comfort in making the diagnosis of anxiety was highly associated with use of selective serotonin reuptake inhibitors. The vast majority (96%) of pediatricians provided nonmedication interventions, including supportive counseling, education for coping with ADHD, behavior modification, and/or stress management. Diagnosis and treatment of severe behavioral health disorders were infrequent throughout the pediatric practices. Areas of greatest educational interest included psychopharmacology, diagnosis and treatment of depression and anxiety, and updates on ADHD. The majority of pediatric providers did not identify a need for education about several high-prevalence disorders that they do not frequently diagnose or treat, including conduct disorder and substance abuse. **CONCLUSIONS:** Pediatricians in this sample frequently diagnosed and treated ADHD. For all other behavioral health disorders, pediatricians reported variability in both comfort and practice. They frequently provided both pharmacologic and nonpharmacologic treatments for children and adolescents with mild to moderate behavioral health disorders but not for severe disorders. Although they identified needs for additional education for anxiety and depression, the majority did not identify educational needs for several high-prevalence behavioral health disorders, including conduct disorder and substance abuse.

Williams O, Forster G, Robinson A. Screening for sexually transmitted infections in children and adolescents in the United Kingdom: British Co-operative Clinical Group. *Int J STD AIDS* 2001; 12(8):487-92. Abstract: Our objectives were (1) to assess the number of young people aged under 16 years attending genitourinary medicine (GUM) departments in the UK in 1998; (2) to identify clinical activity and policy; (3) to determine the knowledge and training needs of healthcare professionals within GUM providing care for this client group. In July 1999 a questionnaire was circulated via the 18 regional British Co-operative Clinical Group (BCCG) representatives to the consultants in charge of all 197 main GUM departments in the UK. One hundred and sixty out of 197 (81%) completed questionnaires were returned and analysed. The reported number of under-16-year-olds attending in 1998 varied considerably between clinics; for females ranging from 0 to 256 and for males between 0 and 50, with a male to female ratio of 1:4.4. The majority of responding clinics, 139/160 (87%) had been involved in the screening of abused children/adolescents for sexually transmitted infections (STIs). Most clinics were prepared to screen for STI (86%), HIV test (79%) and assess contraceptive needs (50%) in this age group. Staff involved in care included health advisers (74), nurses (59), and doctors (138) in the responding clinics. Only 31/160 clinics (19%) had a written policy for the management of children/adolescents attending their clinic. The majority of respondents were aware of their child protection policy [122/154 (79%)] and designated child sexual abuse doctor, [125/157 (80%)] in their district. When questioned on previous and current training needs, 134/160 (84%) respondents identified their need for further training in the area of adolescent sexual health and 124/160 (78%) in child sex abuse. The publication *Physical Signs of Sexual Abuse in Children*, was known to 112/160 (70%) respondents, of whom 58/112 (52%) who answered this question had read the publication. Genitourinary physicians in the UK are aware of the increasing number of children and adolescents accessing their services, and recognize the need to identify those in abusive situations. Written policies dealing with children and adolescents in GUM clinics in the UK are lacking. This needs to be rectified urgently. This survey identifies that further training in the field of child sexual abuse and adolescent sexual health would be welcomed by the respondents.

Williams WG. Surgical outcomes in congenital heart disease: expectations and realities. *Eur J Cardiothorac Surg* 2005; 27(6):937-44. Abstract: The past 50 years of congenital heart surgery has produced enormous progress. Current results surpass expectations. Yet there are important residual problems in patients growing up after heart surgery for congenital heart disease. Our system of care must evolve to care for these people throughout their lives. The evolution of congenital heart surgery has reached a

point in time when we should extend care to patients in under serviced emerging countries. Development of local expertise will be required within those countries that are willing to commit resources to an organized program of caring for people with congenital heart disease. Database technology is an essential tool for ensuring and improving quality of care in every congenital heart centre. Both Registry and Academic databases have much to offer in improving care for future patients. Yet overzealous privacy laws threaten the knowledge base provided by computerized databases. We need to guide our legislators in ensuring that the valuable resource provided by database technology is not lost.

Williamson MA, Johnston CA, Symes SA, Schultz JJ. Interpersonal violence between 18th century Native Americans and Europeans in Ohio. *Am J Phys Anthropol* 2003; 122(2):113-22. Abstract: During the winter of 1778-1779, a garrison of 176 individuals lived within the walls of a Revolutionary era stronghold named Ft. Laurens on the banks of the Tuscarawas River, near the present-day town of Bolivar, Ohio. At least 21 individuals were buried in the fort's cemetery during its occupation, 13 of whom were supposedly killed and scalped by Native Americans while gathering firewood and foraging horses. The purpose of this study is to build on previous work by Sciulli and Gramly ([1989] *Am J. Phys. Anthropol.* 80:11-24) by adding a more detailed analysis of the traumatic lesions, in order to better understand what happened to the victims. Lesions were analyzed based on type, location, and dimensions, as well as their overall pattern on the skeleton. Results indicate that multiple blows to the cranium were common. Out of 12 observable crania, the order of blows could be determined in only one case. Eleven of 12 of the observable crania from ambush victims and four of the seven nonambush victims exhibited lesions consistent with scalping. Evidence of postcranial trauma was noted on four individuals: one was an ambush victim, and the other three were killed at other times. No evidence of gunshot wounds was found.

Williamson R. The balance between privacy, safety and community health. *J Paediatr Child Health* 2003; 39(7):507-8.

Willock J, Askew C, Bolland R, Maciver H, James N. Multicentre research: lessons from the field. *Paediatr Nurs* 2005; 17(10):31-3. Abstract: Multicentre research can be used to explore and generate significant data in aspects of care that affect small numbers of children. This article describes the problems and benefits encountered by a group of nurses from 11 hospitals undertaking a multicentre study of pressure ulcers in children and young people in England and Wales. Multicentre research can generate a large amount of useful data contributing to

high quality evidence-based care and can provide nurses with a valuable learning and networking experience.

Wills TA, Resko JA, Ainette MG, Mendoza D. Role of parent support and peer support in adolescent substance use: a test of mediated effects. *Psychol Addict Behav* 2004; 18(2):122-34.

Abstract: This research tested comparative effects of parent and peer support on adolescent substance use (tobacco, alcohol, and marijuana) with data from 2 assessments of a multiethnic sample of 1,826 adolescents, mean age 12.3 years. Multiple regression analyses indicated that parental support was inversely related to substance use and that peer support was positively related to substance use, as a suppression effect. Structural modeling analyses indicated that effects of support were mediated through pathways involving good self-control, poor self-control, and risk-taking tendency; parent and peer support had different patterns of relations to these mediators. The mediators had pathways to substance use through positive and negative recent events and through peer affiliations. Effects for gender and ethnicity were also noted. Mechanisms of operation for parent and peer support are discussed.

Wills TA, Sandy JM, Yaeger AM. Stress and smoking in adolescence: a test of directional hypotheses. *Health Psychol* 2002; 21(2):122-30.

Abstract: The authors conducted a comparative test of the hypotheses that (a) stress is an etiological factor for smoking and (b) cigarette smoking causes increases in stress (A. C. Parrott, 1999). Participants were a sample of 1,364 adolescents, initially surveyed at mean age 12.4 years and followed at 3 yearly intervals. Measures of negative affect, negative life events, and cigarette smoking were obtained at all 4 assessments. Latent growth modeling showed negative affect was related to increase in smoking over time; there was no path from initial smoking to change in negative affect. Comparable results were found for negative life events, with no evidence for reverse causation. Results are discussed with respect to theoretical models of nicotine effects and implications for prevention.

Wills TA, Sandy JM, Yaeger AM. Time perspective and early-onset substance use: a model based on stress-coping theory. *Psychol Addict Behav* 2001; 15(2):118-25.

Abstract: This research tested the relation of time perspective to early-onset substance use (tobacco, alcohol, and marijuana) with a sample of 454 elementary school students with a mean age of 11.8 years. An adaptation of the Zimbardo Time Perspective Inventory (P. G. Zimbardo & J. N. Boyd, 1999) was administered with measures derived from stress-coping theory. Independent effects showed future orientation inversely related to substance use and present

orientation positively related to substance use. Structural modeling analysis indicated that the relation of time perspective measures to substance use was indirect, mediated through behavioral coping and anger coping. Proximal factors for substance use were negative affect, peer substance use, and resistance efficacy. Results are discussed with respect to epigenetic models and the role of executive functions in self-control ability.

Wills TA, Sandy JM, Yaeger AM, Cleary SD, Shinar O. Coping dimensions, life stress, and adolescent substance use: a latent growth analysis. *J Abnorm Psychol* 2001; 110(2):309-23.

Abstract: The relation of seven coping dimensions to substance (tobacco, alcohol, marijuana) use was tested with a sample of 1,668 participants assessed at mean age 12.5 years and two yearly follow-ups. An associative latent-growth model showed one index of engagement (behavioral coping) to be inversely related to initial level of adolescent use and growth over time in peer use. Three indices of disengagement (anger coping, helpless coping, and hangout coping) were positively related to initial levels of peer use and adolescent use and to growth in adolescent use. Life stress was positively related to initial levels for peer use and adolescent use and to growth in adolescent use. Moderation tests indicated that effects of coping were significantly greater at higher level of stress; behavioral coping buffered the effects of disengagement. Effects of life stress were greater for girls than for boys. Results are discussed with reference to mechanisms of coping-substance use relationships.

Willumsen E, Hallberg L. Interprofessional collaboration with young people in residential care: some professional perspectives. *J Interprof Care* 2003; 17(4):389-400.

Abstract: The article discusses interprofessional collaboration with young people experiencing psychosocial problems living in residential care in Norway. The professionals involved (n = 23) were social workers, psychologists, teachers, doctors/psychiatrists, unqualified graduates and other staff. The aim was to explore the professionals' contributions and grasp a sense of the wholeness of the collaboration process. A grounded theory approach was applied. During the analysis five categories emerged regarding professionals contributions; knowledge of own and others' agency/service, problem perception, priority, commitment and space for action. Three categories emerged regarding interprofessional interaction; building networks, developing trust and using flexibility. The core category was identified as 'readiness to act'. The findings show an apparent contradiction between health and social policy that encourages the standardisation of services and responding flexibly to the needs of young people for 'tailor made' solutions through access to a range of services. A further finding was extensive use of

flexibility and willingness to go beyond boundaries leading to the distinction between routinized and radical coordination.

Wilmshurst LA. Treatment programs for youth with emotional and behavioral disorders: an outcome study of two alternate approaches. *Ment Health Serv Res* 2002; 4(2):85-96.

Abstract: Youth with severe emotional and behavioral disorders (EBD) were randomly assigned for 3 months of intensive treatment to a 5-day residential program (5DR Program) or a community-based alternative, family preservation program (FP Program). Programs differed not only in method of service delivery (residential unit vs. home-based), but also in treatment philosophy (solution focused brief therapy vs. cognitive behavioral). Results confirmed high rates of comorbidity in this population for externalizing and internalizing disorders. A significant Treatment x Program interaction was evident for internalizing disorders. At 1-year follow-up, significantly higher percentages of youth from the FP Program revealed a reduction of clinical symptoms for ADHD, as well as, general anxiety and depression, whereas significant proportion of youth from the 5DR Program demonstrated clinical deterioration and increased symptoms of anxiety and depression. Results have implications for future treatment of youth with EBD and suggest that greater emphasis be placed on research linking treatment to specific symptom clusters, especially highly comorbid clusters in this hard to serve population.

Wilsnack SC, Wonderlich SA, Kristjanson AF, Vogeltanz-Holm ND, Wilsnack RW. Self-reports of forgetting and remembering childhood sexual abuse in a nationally representative sample of US women. *Child Abuse Negl* 2002; 26(2):139-47.

Abstract: OBJECTIVE: The purpose of this article is to describe patterns of forgetting and remembering childhood sexual abuse (CSA) in a nationally representative sample of US adult women. METHOD: The respondents were a national probability sample of 711 women, aged 26 years to 54 years, residing in noninstitutional settings in the contiguous 48 states. In a 1996 face-to-face interview survey, trained female interviewers asked each respondent whether she had experienced any sexual coercion by family members or nonfamily members while growing up; whether she believed that she had been sexually abused (by family members or others); and whether she had ever forgotten the CSA experiences and, if so, how she had subsequently remembered them. RESULTS: Twenty-one and six-tenths percent of respondents reported having sexually coercive experiences while growing up; of these, 69.0% indicated that they felt they had been sexually abused. More than one-fourth of respondents who felt sexually abused reported that they had forgotten the abuse for some period of time but later remembered it on their own. Only 1.8% of women

self-described as sexually abused reported remembering the abuse with the help of a therapist or other professional person. CONCLUSIONS: The findings indicate that, among women who report CSA, forgetting and subsequently remembering abuse experiences is not uncommon. According to the women surveyed, however, very few (1.8%) of those who felt abused recovered memories of CSA with help from therapists or other professionals. As one of the few studies of CSA memories in a nationally representative sample, this study suggests that therapist-assisted recall is not a major source of CSA memories among women in the US general population.

Wilson J. Family breakdown - how important is it for British general practice? *Br J Gen Pract* 2004; 54(504):558-9.

Wilson JJ, Pine DS, Cargan A, Goldstein RB, Nunes EV, Weissman MM.

Neurological soft signs and disruptive behavior among children of opiate dependent parents. *Child Psychiatry Hum Dev* 2003; 34(1):19-34. Abstract: The present study investigates the relationship between neurological soft signs and psychiatric symptoms among children of opiate dependent parents. A consecutive series of 102 children of opiate dependent parents received standardized psychiatric and neurological assessments. Symptoms of externalizing but not internalizing disorders associated with poor performance on the soft sign exam, controlling for age, intelligence, and socioeconomic status. Given the importance of externalizing disorders in the development of substance use disorders, studies of children at high risk for substance use disorder should also consider screening and assessment of children for soft neurological signs.

Wilson P, McConnachie A, O'Donnell CA, Ross S, Moffat KJ, Drummond N. Assessing dissatisfaction with an out of hours service: reasons and remedies. *Health Bull (Edinb)* 2001; 59(1):37-44.

Abstract: OBJECTIVE: To identify characteristics associated with dissatisfaction following contact with an out of hours co-operative in Glasgow, and to identify reasons for this dissatisfaction. To make recommendations for good practice in the light of these findings. DESIGN: Survey of attenders during one week of operation of an out of hours co-operative. Analysis of factors associated with dissatisfaction. SETTING: The Glasgow Emergency Medical Service, October 1996. SUBJECTS: Questionnaires were received from 1115 patients or their carers, representing a 69.3% response rate. RESULTS: Dissatisfaction was associated with unmet expectations, particularly among those expecting home visits. Parents of young children, more affluent patients, and those experiencing problems with daytime services also tended to be dissatisfied. Seventy four (7%) respondents indicated that they were very dissatisfied with aspects of the service. A high

proportion of this dissatisfaction was related to telephone contact. Transport to out of hours centres caused problems for some patients, particularly for those with young children. Perceptions of dismissive attitudes by medical staff, and of incorrect diagnoses and treatment were causes of strong dissatisfaction. Patients with adverse medical outcomes were also likely to be very dissatisfied. **CONCLUSION:** Clear reasons for dissatisfaction were found among our sample. In most cases, remedial management action could be taken to reduce the likelihood of major dissatisfaction with the service.

Wimmer H, Hutzler F, Wiener C. Children with dyslexia and right parietal lobe dysfunction: event-related potentials in response to words and pseudowords. *Neurosci Lett* 2002; 331(3):211-3. Abstract: Hari and Renvall (*Trends Cogn. Sci.*, 5 (2001) 525) proposed that dyslexic children suffer from sluggish attention deployment due to a right parietal lobe dysfunction. To examine this hypothesis, good and poor readers (12, 11-year-old boys in each group) had to read familiar words (low attentional demand) and pseudowords (high attentional demand). The amplitude of the event-related potential at around 100 ms post-stimulus (N1) in response to words and pseudowords was used as measure of attention deployment. Consistent with the attention deficit/right parietal lobe dysfunction hypothesis, poor readers showed lower N1 amplitudes in response to pseudowords, but not in response to words at central sites of the right hemisphere. However, poor readers also showed lower N1 amplitudes to both words and pseudowords at left frontal sites suggestive of an early deficit in activating phonological codes.

Wind M, Bobelijn K, De Bourdeaudhuij I, Klepp KI, Brug J. A qualitative exploration of determinants of fruit and vegetable intake among 10- and 11-year-old schoolchildren in the low countries. *Ann Nutr Metab* 2005; 49(4):228-35. Abstract: **BACKGROUND:** For the development of fruit and vegetable promotion interventions, insight is needed into determinants of health behaviour. This study presents results of focus group interviews held with 10- to 11-year-old schoolchildren from Ghent (Belgium-Flanders) and Rotterdam (the Netherlands) to explore personal beliefs and motivations and environmental factors related to schoolchildren's fruit and vegetable intake, to inform the Pro Children intervention development. **METHODS:** Twelve focus groups were held with 92 schoolchildren. The interviews were recorded and transcribed and NVivo was used to analyse the transcripts. **RESULTS:** Positive health beliefs, taste preferences, lack of knowledge and practical barriers were identified as personal factors related to fruit and vegetable intake. Home and school availability of fruits and vegetables, as well as parenting practices were identified as important environmental factors. **CONCLUSION:** A

fruit and vegetable promotion intervention should aim to increase fruit and vegetable accessibility and should include educational and motivational activities tailored to these personal and environmental factors. These indications should be further evaluated in quantitative research among representative samples.

Wise LA, Zierler S, Krieger N, Harlow BL. Adult onset of major depressive disorder in relation to early life violent victimisation: a case-control study. *Lancet* 2001; 358(9285):881-7. Abstract: **BACKGROUND:** Major depressive disorder is a significant cause of morbidity among women in the USA. Women are twice as likely as men to be diagnosed with major depressive disorder, yet no known risk factors can account for this sex difference. We aimed to assess violent victimisation as a risk factor for depression in women. **METHODS:** We undertook a case-control study to assess the association between violent victimisation early in life and major depressive disorder in women. We randomly selected a population-based sample of women, aged 36-45 years, from the greater Boston area. In 1999, 236 cases and 496 controls (n=732) completed a self-administered questionnaire designed to ascertain a lifetime history of exposure to violent victimisation. Our main outcome measure was major depressive disorder, assessed by structured clinical interview for Diagnostic Statistical Manual IV (DSM-IV) criteria. **FINDINGS:** 363 (50%) of 732 respondents reported experience or fear of abuse as a child or adolescent. 68 were excluded because they reported violence as an adult only. Compared with women who reported no abuse, risk of depression was increased in women who reported any abuse as a child or adolescent (relative risk 2.5, 95% CI 1.9-3.0), physical abuse only (2.4, 1.8-3.0), sexual abuse only (1.8, 1.2-2.8), and both physical and sexual abuse (3.3, 2.5-4.1). Severity of abuse had a linear dose-response relation with depression. **INTERPRETATION:** Our results suggest a positive association between violent victimisation early in life and major depressive disorder in women.

Wise PH. The transformation of child health in the United States. *Health Aff (Millwood)* 2004; 23(5):9-25. Abstract: Social trends and medical progress have fueled major changes in the epidemiology of child health in the United States. Injuries remain a major contributor to childhood illness and death. However, among noninjury causes, chronic illness now accounts for the majority of children's hospital days and deaths. Although mortality rates for all children have fallen dramatically, social disparities persist. Approximately half of all excess deaths among African American children occur during infancy, primarily from extremely premature births, and the remaining portion, primarily from homicide and serious chronic conditions. These challenges may require changes in today's child health practices and policies.

Wolak J, Finkelhor D, Mitchell K. Internet-initiated sex crimes against minors: implications for prevention based on findings from a national study. *J Adolesc Health* 2004; 35(5):424.e11-20. Abstract: PURPOSE: To describe the characteristics of episodes in which juveniles became victims of sex crimes committed by people they met through the Internet. METHODS: A national survey of a stratified random sample of 2574 law enforcement agencies conducted between October 2001 and July 2002. Telephone interviews were conducted with local, state, and federal law enforcement investigators concerning 129 sexual offenses against juvenile victims that originated with online encounters. RESULTS: Victims in these crimes were primarily 13- through 15-year-old teenage girls (75%) who met adult offenders (76% older than 25) in Internet chat rooms. Most offenders did not deceive victims about the fact that they were adults who were interested in sexual relationships. Most victims met and had sex with the adults on more than one occasion. Half of the victims were described as being in love with or feeling close bonds with the offenders. Almost all cases with male victims involved male offenders. Offenders used violence in 5% of the episodes. CONCLUSIONS: Health care professionals and educators, parents and media need to be aware of the existence, nature and real life dynamics of these online relationships among adolescents. Information about Internet safety should include frank discussion about why these relationships are inappropriate, criminal, and detrimental to the developmental needs of youth.

Wolak J, Mitchell KJ, Finkelhor D. Escaping or connecting? Characteristics of youth who form close online relationships. *J Adolesc* 2003; 26(1):105-19. Abstract: We used data from a US national sample of Internet users, ages 10-17 (N=1501), to explore the characteristics of youth who had formed close relationships with people they met on the Internet (n=210). Girls who had high levels of conflict with parents or were highly troubled were more likely than other girls to have close online relationships, as were boys who had low levels of communication with parents or were highly troubled, compared to other boys. Age, race and aspects of Internet use were also related. We know little about the nature or quality of the close online relationships, but youth with these sorts of problems may be more vulnerable to online exploitation and to other possible ill effects of online relationships. At the same time, these relationships may

have helpful aspects.

Wolchik SA, Sandler IN, Millsap RE *et al*. Six-year follow-up of preventive interventions for children of divorce: a randomized controlled trial. *JAMA* 2002; 288(15):1874-81.

Abstract: CONTEXT: Compared with their peers with nondivorced parents, adolescents with divorced parents are more likely to have mental health problems, drop out of school, and become pregnant. The long-term effects of intervention programs for this population are unknown. OBJECTIVE: To evaluate the long-term effectiveness of 2 programs designed to prevent mental health problems in children with divorced parents. DESIGN AND SETTING: Six-year follow-up of a randomized controlled trial of 2 intervention programs (mother program: 11 group and 2 individual sessions; mother plus child program: mother program and 11 group sessions for children) and a control condition (books on postdivorce adjustment), which was conducted in a large metropolitan US city from April 1998 through March 2000. PARTICIPANTS: A total of 218 families (91% of the original sample) with adolescents aged between 15 and 19 years were reinterviewed. MAIN OUTCOME MEASURES: Externalizing and internalizing problems, diagnosed mental disorders, drug and alcohol use, and number of sexual partners. RESULTS: Eleven percent of adolescents in the mother plus child program (95% confidence interval [CI], 3.8%-18.2%) had a 1-year prevalence of diagnosed mental disorder compared with 23.5% (95% CI, 13.8%-33.2%) of adolescents in the control program (P =.007). Adolescents in the mother plus child program had fewer sexual partners (mean [SE], 0.68 [0.16]) compared with adolescents in the control program (1.65 [0.37]; P =.01). Adolescents with higher initial mental health problems whose families were in the mother plus child program had lower externalizing problems (P =.007) and fewer symptoms of mental disorder (P =.02) compared with those in the control program. Compared with controls, adolescents whose mothers participated in the mother program and who had higher initial mental health problems had lower levels of externalizing problems (P<.001); fewer symptoms of mental disorder (P =.005); and less alcohol (P =.005), marijuana (P =.02), and other drug use (P =.01). CONCLUSIONS: In adolescents of divorced parents, the mother program and the mother plus child program reduced symptoms of mental disorder; rates of diagnoses of mental disorder; levels of externalizing problems; marijuana, alcohol, and other drug use; and number of sexual partners.

Wolf LE, Lo B, Beckerman KP, Dorenbaum A, Kilpatrick SJ, Weintrub PS. When parents reject interventions to reduce postnatal human immunodeficiency virus transmission. *Arch Pediatr Adolesc Med* 2001; 155(8):927-33.

Abstract: In a recent Oregon case, the state successfully

sued for custody of an infant to prevent his human immunodeficiency virus (HIV)-infected mother from breastfeeding him and to require antiretroviral prophylaxis. As more HIV-infected women give birth, pediatricians may increasingly face dilemmas when parents reject medical recommendations to forego breastfeeding and to administer antiretroviral prophylaxis to the infant. Such disagreements create ethical dilemmas because pediatricians have an obligation to both protect the infant and respect parental decision making. Pediatricians need to balance these obligations in deciding whether to ask the courts to intervene on the infant's behalf. To that end, we analyze the legal and ethical issues that arise when an HIV-infected mother refuses interventions to reduce neonatal transmission of HIV to her infant, provide an approach for addressing these disagreements, and present illustrative scenarios in which pediatricians should, may, and should not seek a court order to intervene.

Wolf RC, Bond KC. Exploring similarity between peer educators and their contacts and AIDS-protective behaviours in reproductive health programmes for adolescents and young adults in Ghana. *AIDS Care* 2002; 14(3):361-73.  
Abstract: This analysis explores the similarity between peer educators and their contacts. To examine interpersonal communication in the context of peer education, this study tested a new approach using multiple semi-structured interviews and network analysis to collect data from 106 peer educators and 526 of their contacts. These evaluation activities were conducted at three sites in Ghana during April 1998, in peri-urban and rural locations, and in in-school and out-of-school targeted settings. It was found that in their peer counselling and peer promotion activities peer educators tend to reach people who are like themselves (53% within 2 years of age, 59% same sex, 70% same ethnicity, and 65% same school status) however, this trend is not uniform among all youth and varies by demographic characteristics and their cultural environment. By examining the social networks of peer educators, it is possible to gain a better understanding of the process of peer education counselling in the context in which it occurs. The study also shows that controlling for other factors, contacts of peer educators who are highly similar regarding age, sex, ethnicity, and school status, are 1.74 times more likely (95% CI: 1.18, 2.56) to have done something to protect themselves from AIDS in the past three months. The results have relevance for programme managers and planners, researchers, and international agencies serving youth.

Wolfe DA, Scott K, Wekerle C, Pittman AL. Child maltreatment: risk of adjustment problems and dating violence in adolescence. *J Am Acad Child Adolesc Psychiatry* 2001; 40(3):282-9.  
Abstract: OBJECTIVE: To examine the relationship

between child maltreatment, clinically relevant adjustment problems, and dating violence in a community sample of adolescents. METHOD: Adolescents from 10 high schools (N= 1,419; response rate = 62%) in southwestern Ontario completed questionnaires that assessed past maltreatment, current adjustment, and dating violence. Logistic regression was used to compare maltreated and nonmaltreated youths across outcome domains. RESULTS: One third (n = 462) of the school sample reported levels of maltreatment above the cutoff score on the Childhood Trauma Questionnaire. Girls with a history of maltreatment had a higher risk of emotional distress compared with girls without such histories (e.g., odds ratios [OR] for anger, depression, anxiety, and posttraumatic stress-related problems were 7.1, 7.2, 9.3, and 9.8, respectively). They were also at greater risk of violent and nonviolent delinquency (OR = 2.7) and carrying concealed weapons (OR = 7.1). Boys with histories of maltreatment were 2.5 to 3.5 times as likely to report clinical levels of depression, posttraumatic stress, and overt dissociation as were boys without a maltreatment history. They also had a significantly greater risk of using threatening behaviors (OR = 2.8) or physical abuse (OR = 3.4) against their dating partners. CONCLUSIONS: Maltreatment is a significant risk factor for adolescent maladjustment and shows a differential pattern for male and female adolescents.

Woltersdorf M. [Post-traumatic stress disorder in police with long-term exposure to homicide and child abuse. A previously unrecognized occupational disease exemplified by 2 case reports]. *Psychiatr Prax* 2003; 30 Suppl 2:S88-9.  
Abstract: In this paper we discuss two cases of PTSD of policemen according to their occupational duties.

Wolfram-Gabel R, Sery FG, Sick H. Microvascularisation of the male urethra in neonates and infants. *Surg Radiol Anat* 2004; 26(6):488-93.  
Abstract: The microvascularisation of the male urethra was studied in neonates and infants by injection of agarised China ink into the circulation. The purpose of this study was to specify the angioarchitecture of each tunic of the urethral wall. The disposition of the microvascularisation networks varies depending on the urethral parts considered: only the mucous membrane networks are uniform throughout the entire urethra. The sub-mucous networks are significantly increased in the spongy part. The muscular networks disappear in the spongy part.

Wolfram-Gabel R, Sick H. Microvascularization of the mucocutaneous junction of the eyelid in fetuses and neonates. *Surg Radiol Anat* 2002; 24(2):97-101.  
Abstract: The aim of this study was to specify the microvascularization of the junctional region between the integuments of the superficial surface of the free

margin of the eyelid and the palpebral conjunctival mucosa. The study was carried out using histological or transparified slices of upper and lower eyelids taken from fetuses and neonates, in which the vascular system was injected with agarized China ink. The mucocutaneous junction of the eyelid is located at the posterior border of the free margin and extends to its deep surface. It has vascular similarities to the oral cavity and the nasal pyramid. Under a thickened avascular epithelium, there is a papillary network composed of characteristic loops that are less raised than in the lips but more developed than in the nose. The superficial and deep vascular reticular networks are comparable in fundamental arrangement to those of other junctional zones. Thus, the palpebral mucocutaneous junction shows cutaneous-type microvascularization, just like the other junctional zones of the head.

Wolfram-Gabel R, Sick H. Microvascularization of the mucocutaneous junction of the nose. *Surg Radiol Anat* 2002; 24(1):27-32.

Abstract: The aim of this study was to describe the microvascularization of the area of junction located between the integuments of the nasal ala and the respiratory mucosa. This study is part of an overall study on the microvascularization of the mucocutaneous junctions of the head. It was undertaken on histological or clarified sections of noses from fetuses, newborns and adults whose vascular system was injected with Indian ink agar. The mucocutaneous junction of the nose shows similarities with the mucocutaneous junction of the oral cavity. Under a well-defined avascular and thick epithelium lies a vascular papillary network with typical loops less high than in the lips. The angioarchitectonics of superficial and deep vascular reticular networks is similar to that of the lips but they are less dense.

Wolfram-Gabel R, Sick H. Microvascularization of the mucocutaneous junctions of the head in fetuses and neonates. *Cells Tissues Organs* 2002; 171(4):250-9.

Abstract: The mucocutaneous junctions of the head (oral, nasal and palpebral) are transitional zones between the integuments and the mucosa. Their microvascularization is studied in the heads of fetuses and neonates by injection of agarized China ink into the vascular system. These zones are situated deep with respect to the free edge of the oral or nasal cavity or relative to the free margin of the eyelid. They present cutaneous-type microvascularization with a papillary network and reticular networks. Long capillary loops connected to the deep reticular network are their main feature. In the lips and eyelids, the morphology of the networks and their relationship with the orbicular muscles are suggestive of a functional structure.

Wolfson DR, McNally DS, Clifford MJ, Vloeberghs M. Rigid-body modelling of shaken baby syndrome. *Proc*

*Inst Mech Eng [H]* 2005; 219(1):63-70.

Abstract: Recent reassessment of the literature on the shaken baby syndrome (SBS) has revealed a lack of scientific evidence and understanding of all aspects of the syndrome. In particular, studies have been unable to clarify the mechanisms of injury, indicating that impact, rather than shaking alone, is necessary to cause the type of brain damage observed. Rigid-body modelling (RBM) was used to investigate the effect of neck stiffness on head motion and head-torso impacts as a possible mechanism of injury. Realistic shaking data obtained from an anthropometric test dummy (ATD) was used to simulate shaking. In each study injury levels for concussion were exceeded, though impact-type characteristics were required to do so in the neck stiffness study. Levels for the type of injury associated with the syndrome were not exceeded. It is unlikely that further gross biomechanical investigation of the syndrome will be able to significantly contribute to the understanding of SBS. Current injury criteria are based on high-energy, single-impact studies. Since this is not the type of loading in SBS it is suggested that their application here is inappropriate and that future studies should focus on injury mechanisms in low-energy cyclic loading.

Wolke D, Samara MM. Bullied by siblings: association with peer victimisation and behaviour problems in Israeli lower secondary school children. *J Child Psychol Psychiatry* 2004; 45(5):1015-29.

Abstract: BACKGROUND: The association of bullying victimisation by siblings with a) involvement in bullying at school and b) behaviour problems among lower secondary school children in Israel was investigated. METHOD: Self-report questionnaires of sibling victimisation, peer bullying experiences and behaviour problems were completed by 921 pupils aged 12-15 (mean age 13.7 years). RESULTS: Of the sample, 16.2% were directly bullied by their siblings at home and 11.9% were direct victims of bullying by peers at school every week. More than half of victims of bullying by siblings (50.7%) were also involved in bullying behaviour at school compared to only 12.4% of those not victimised by siblings, indicating a strong link between intrafamilial and extrafamilial peer relationships. Children with poor sibling and peer relationships were at a highly increased risk for behaviour problems. Ethnic (Israeli Jewish vs. Arab) and sex differences were small compared to the effects of sibling relationship on behaviour problems. CONCLUSION: Intervention strategies directed at reducing bullying in school should take into account pupils' experiences of victimisation by siblings at home.

Wolke D, Woods S, Stanford K, Schulz H. Bullying and victimization of primary school children in England and Germany: prevalence and school factors. *Br J Psychol* 2001; 92(Pt 4):673-96.

Abstract: Differences in definitions and methodologies

for assessing bullying in primary school children between countries have precluded direct comparisons of prevalence rates and school factors related to bullying. A total of 2377 children in England (6-year-olds/Year 2: 1072; 8-year-olds/Year 4: 1305) and 1538 in Germany (8-year-olds/Year 2) were questioned individually using an identical standard interview. In both countries the types of bullying to victimize others were similar: boys were most often perpetrators, most bullies were also victims (bully/victims), most bullying occurred in playgrounds and the classroom, and SES and ethnicity only showed weak associations with bullying behaviour. Major differences were found in victimization rates with 24% of English pupils becoming victims every week compared with only 8% in Germany. In contrast, fewer boys in England engaged every week in bullying (2.5-4.5%) than German boys (7.5%), while no differences were found between girls. In England, children in smaller classes were more often victimized. Further study of the group of bully/victims, schooling differences in England vs. Germany and implications for prevention of bullying are discussed.

Woller W, Kruse J. [Personality disorders and psychopathology following trauma. Reflection on diagnostic classification]. *Nervenarzt* 2003; 74(11):972-6.

Abstract: Pervasive personality disorders have been shown to be long-term sequelae of cumulative childhood physical and sexual traumatization. This finding is not reflected in DSM-IV and ICD-10 classifications where post-traumatic stress disorder is confined to intrusions, avoidance, numbing, and hyperarousal. However, there is growing evidence that trauma etiology should be taken into account in planning treatment for personality disorders. It is not yet clear whether childhood traumatization is more strongly associated with borderline personality disorder than with other personality disorders. The finding of a substantial overlap between borderline personality disorder and dissociative identity disorder gives rise to discussions concerning the relationship of these two pathologies.

Wong JP, Stewart SM, Ho SY, Rao U, Lam TH. Exposure to suicide and suicidal behaviors among Hong Kong adolescents. *Soc Sci Med* 2005; 61(3):591-9. Abstract: Suicidal behaviors (deliberate self-injury with the intent to hurt or kill oneself) have been little examined outside the West. The aims of this study were to (a) determine the correlates of suicidal behaviors, and (b) examine whether depression and suicide ideation moderated the effects of exposure to completed and attempted suicide on suicidal behaviors among a community sample of Hong Kong youth ages 12-17. Adolescents responded to questions regarding self-injurious behaviors, and also indicated presence of intention to hurt or kill themselves in the past 12 months. Based on their responses, two groups of

interest were formed: 96 youths reported both self-injurious behaviors and the intent to hurt or kill themselves, and formed the "suicidal behaviors" group; and, 1213 adolescents reported neither self-injurious behaviors nor intent to hurt self or die, and formed the control group. The participants also responded to questions about depressive symptoms, anxiety, suicidal ideation and attempt, alcohol/drug use, stressful life events, and family relationships. They indicated whether anyone they knew had attempted or completed suicide in the previous 12 months. Logistic regression indicated that depressive symptoms, stressful life events, suicidal ideation and exposure to suicide attempt (but not completed suicide) contributed unique variance to the presence of suicidal behaviors, after controlling for demographic variables. Depression (and at trend levels, suicidal ideation) moderated the effect of exposure to suicide attempt by others on suicidal behaviors. Our results indicate that completed suicide in the social network increases risk for suicidal behaviors, but not when other risk factors are controlled. By contrast, a suicide attempt independently increases risk for suicidal behaviors. Furthermore, those youths who experience depressive symptoms or suicidal ideation are at particularly high risk for engaging in suicidal behaviors when an exposure to suicide attempt occurs.

Wong WC. Acceptability study of sex workers attending the HIV/ AIDS clinic in Ruili, China. *Asia Pac J Public Health* 2003; 15(1):57-61.

Abstract: A charitable clinic was set up to provide HIV/STD education and care to commercial sex workers in Ruili. Despite regular promotion of the clinic, few people had utilised the service. Therefore, a qualitative study was carried out among 89 sex workers between March and April 2001 to look at the background of our target group, their medical-seeking behaviours and the range of services expected. The turnover rates of sex workers were high. They had good awareness but poor knowledge of STD/HIV. Many self-medicated or sought advice from peers. They had a serious concern for private practitioners or the quality of drugs from pharmacy stores. They found our clinic inconvenient and did not meet their needs. Subsequently, we refurbished the clinic, implemented changes and retrained our staff. The number of patients treated three weeks after re-opening of the clinic has increased by three folds, with many of them still sex workers, and the clinic's income increased by 58%. Our experience has important implications for policymakers and other NGOs working with sex workers.

Woo P. Cytokines and juvenile idiopathic arthritis. *Curr Rheumatol Rep* 2002; 4(6):452-7.

Abstract: Cytokines are a large group of polypeptides and small proteins that are effector molecules for cells involved in immune and inflammatory responses. There are agonists and antagonists that interact with each other to maintain a dynamic equilibrium, and

ensure eventual recovery of any perturbation, for example, by trauma or infection, of the network toward inflammation. The imbalance between pro- and anti-inflammatory cytokines and the T helper cell subtypes is considered important in the pathogenesis of autoimmune diseases, including juvenile idiopathic arthritis. The measurement of cytokines and chemotactic cytokines in body fluids and synovial tissue has provided insight into the type of immune and inflammatory reaction and the possible presence or absence of regulation. Differences between subtypes of juvenile idiopathic arthritis have been identified with these measurements. But cytokine measurements in serum are not useful for diagnostic purposes, because of the variability during 24 hours, the collection and assay methods, as well as the ease of degradation for most cytokines. The recent interest in the genetic polymorphisms of cytokine genes and their association with juvenile idiopathic arthritis has provided association with a number of cytokine alleles. Confirmation of linkage with disease is only available for tumor necrosis factor and interleukin-6 at present. These genetic variants may be the basis of genetic susceptibility to the persistent imbalance in the inflammatory and immune networks, and determine the phenotype and severity of disease.

Wood D. Effect of child and family poverty on child health in the United States. *Pediatrics* 2003; 112(3 Part 2):707-11.

Abstract: Poverty has been described as an economic state that does not allow for the provision of basic family and child needs, such as adequate food, clothing, and housing. However, the debate about the effects of poverty on the growth, development, and health of children is as much involved with the culture or general context of poverty as it is with the economics of poverty. This culture of poverty is in part mediated through environmental deprivations, such as failing schools, gangs, drugs, violence, and struggling families. Hecl(1) described this sociocultural and environmental dimension of poverty as "a condition of misery, hopelessness, and dependency." The subject of this article is to review the literature on the effects of poverty on US children as mediated through economic, ecologic, and family influences.

Wood DL. Increasing immunization coverage. *American Academy of Pediatrics Committee on Community Health Services. American Academy of Pediatrics Committee on Practice and Ambulatory Medicine. Pediatrics* 2003; 112(4):993-6. Notes: CORPORATE NAME: American Academy of Pediatrics Committee on Community Health Services CORPORATE NAME: American Academy of Pediatrics Committee on Practice and Ambulatory Medicine

Abstract: Despite many recent advances in vaccine delivery, the goal for universal immunization set in 1977 has not been reached. In 2001, only 77.2% of US

toddlers 19 to 35 months of age had received their basic immunization series of 4 doses of diphtheria and tetanus toxoids and acellular pertussis (DTaP) vaccine, 3 doses of inactivated poliovirus vaccine, 1 dose of measles-mumps-rubella (MMR) vaccine, and 3 doses of *Haemophilus influenzae* type b (Hib) vaccine. Children who are members of a racial or ethnic minority, who are poor, or who live in inner-city or rural areas have lower immunization rates than do children in the general population. Additional challenges to vaccine delivery include the introduction of new childhood vaccines, ensuring a dependable supply of vaccines, bolstering public confidence in vaccine safety, and sufficient compensation for vaccine administration. Recent research has demonstrated specific and practical changes physicians can make to improve their practices' effectiveness in immunizing children, including the following: 1) sending parent reminders for upcoming visits and recall notices; 2) using prompts during all office visits to remind parents and staff about immunizations needed at that visit; 3) repeatedly measuring practice-wide immunization rates over time as part of a quality improvement effort; and 4) having in place standing orders for registered nurses, physician assistants, and medical assistants to identify opportunities to administer vaccines. Pediatricians should work individually and collectively at local and national levels to ensure that all children receive all childhood immunizations on time. Pediatricians also can proactively communicate with parents to ensure they understand the overall safety and efficacy of vaccines.

Woodruff TJ, Parker JD, Kyle AD, Schoendorf KC. Disparities in exposure to air pollution during pregnancy. *Environ Health Perspect* 2003; 111(7):942-6.

Abstract: Previous research shows poorer birth outcomes for racial and ethnic minorities and for persons with low socioeconomic status (SES). We evaluated whether mothers in groups at higher risk for poor birth outcomes live in areas of higher air pollution and whether higher exposure to air pollution contributes to poor birth outcomes. An index representing long-term exposure to criteria air pollutants was matched with birth certificate data at the county level for the United States in 1998-1999. We used linear regression to estimate associations between the air pollution index and maternal race and educational attainment, a marker for SES of the mother, controlling for age, parity, marital status, and region of the country. Then we used logistic regression models both to estimate likelihood of living in counties with the highest levels of air pollution for different racial groups and by educational attainment, adjusting for other maternal risk factors, and to estimate the effect of living in counties with higher levels of air pollution on preterm delivery and births small for gestational age (SGA). Hispanic, African-American, and Asian/Pacific Islander mothers experienced higher

mean levels of air pollution and were more than twice as likely to live in the most polluted counties compared with white mothers after controlling for maternal risk factors, region, and educational status [Hispanic mothers: adjusted odds ratio (AOR) = 4.66; 95% confidence interval (95% CI), 1.92-11.32; African-American mothers: AOR = 2.58; 95% CI, 1.00-6.62; Asian/Pacific Islander mothers: AOR = 2.82; 95% CI, 1.07-7.39]. Educational attainment was not associated with living in counties with highest levels of the air pollution index (AOR = 0.95; 95% CI, 0.40-2.26) after adjusting for maternal risk factors, region of the country, and race/ethnicity. There was a small increase in the odds of preterm delivery (AOR = 1.05; 95% CI, 0.99-1.12) but not SGA (AOR = 0.96; 95% CI, 0.86-1.07) in a county with high air pollution. Additional risk of residing in areas with poor air quality may exacerbate health problems of infants and children already at increased risk for poor health.

Woods CR. Syphilis in children: congenital and acquired. *Semin Pediatr Infect Dis* 2005; 16(4):245-57. Abstract: Syphilis rates in women and congenital syphilis rates have declined steadily in the United States in recent years. However, syphilis remains a worldwide public health problem, with more than 12 million cases in adults and more than half a million pregnancies affected yearly. Prenatal screening and treatment programs are limited or nonexistent in many developing countries. The genome of *Treponema pallidum*, one of the smallest among prokaryotes, has been sequenced, but methods for continuous *in vitro* cultivation of the microbe remain elusive. There are no promising candidates for future vaccines at this time. Serologic testing, for both specific treponemal and nontreponemal antibodies, continues to be a primary means of diagnosis. Penicillin remains the drug of choice for congenital and acquired syphilis in childhood. The diagnosis of syphilis beyond early infancy raises concerns for possible child sexual abuse, although progression of congenital syphilis may account for some cases. Syphilis is a potentially eradicable disease, but this can be achieved only with sustained international will and cooperation to fund the necessary screening and treatment programs.

Woolfenden S, Dossetor D, Williams K. Children and adolescents with acute alcohol intoxication/self-poisoning presenting to the emergency department. *Arch Pediatr Adolesc Med* 2002; 156(4):345-8. Abstract: OBJECTIVE: To describe the presentations, characteristics, and follow-up care of children and adolescents aged 10 to 18 years who present to emergency departments (EDs) with acute alcohol intoxication/self-poisoning. DESIGN: Retrospective medical record review. SETTING: Five EDs in Western Sydney, Australia. PARTICIPANTS: Patients aged 10 to 18 years who presented to EDs with acute alcohol intoxication/self-poisoning between January 1, 1996, and December 31, 2000. MAIN OUTCOME

MEASURES: Frequency of presentations; presentation characteristics; psychosocial characteristics; and presence or absence of follow-up. RESULTS: Two hundred twelve children and adolescents presented to EDs 216 times. Of the 212 patients, 49 (23%) were 14 years or younger, and the youngest was aged 10 years. The majority (82%) came after hours and were brought in by emergency services (77%). In 13% of presentations, verbal and/or physical aggression was present, and a threat of self-harm was present in 2% of cases. A mental health worker was consulted about the child or adolescent in only 6% of presentations. Most children and adolescents (85%) were discharged from the ED. Of concern, in 56% of presentations, a follow-up plan was not recorded. There was documentation of mental health follow-up in only 14% of presentations and follow-up from drug and alcohol services in only 1%. Forensic history, school functioning, and a history of past mental health problems were not documented in more than 60% of the medical records examined. CONCLUSIONS: When children or adolescents present to an ED with acute alcohol intoxication/self-poisoning, their risk factors for psychosocial dysfunction appear to be inadequately assessed, documented, and followed up. Clear guidelines for assessment and referral pathways must be established in EDs.

Woollard M, Jewkes F. 5 Assessment and identification of paediatric primary survey positive patients. *Emerg Med J* 2004; 21(4):511-7.

Worku A, Addisie M. Sexual violence among female high school students in Debarq, north west Ethiopia. *East Afr Med J* 2002; 79(2):96-9. Abstract: OBJECTIVES: To assess the prevalence, outcome and awareness of sexual violence among high school female students. DESIGN: A school-based cross-sectional survey. SETTING: Debarq Town, north-west Ethiopia. SUBJECTS: Two hundred and sixteen female high school students, grade 9-11 were included for the quantitative study. For the qualitative data, 16 individuals for the focus group discussion (10 well-recognised female figures in the town and six high school students) and head of the police department for in-depth interview were enrolled. RESULTS: Sixty two per cent of the respondents had heard of sexual violence committed on young females. Sexual violence was reported by 65.3% of the respondents. The prevalence of performed and attempted rape were 8.8% and 11.5%, respectively. The age range of performed rape victims was between 12 and 21 years. Of the 19 (8.8%) who reported rape being performed on them, unwanted pregnancy, suicide attempt, vaginal

discharge and abortion were the consequences in 21%, 15.8%, 10.5% and 5.3%, respectively. CONCLUSION: Sexual violence is a major public health problem with high rates of underreporting. Sex education should be given on a regular basis and policy making bodies and the police be well aware of this high magnitude and take strong measures to reduce it.

Worobey J, Pisuk J, Decker K. Diet and behavior in at-risk children: evaluation of an early intervention program. *Public Health Nurs* 2004; 21(2):122-7. Abstract: This study describes outcomes for children enrolled in the Prevention-Oriented System for Child Health Project, an early intervention program aimed at improving health and developmental status in at-risk families. Through a series of home visits by public health nurses, 60 families received lessons on nutrition- and health-related topics determined by the child and family's needs. On two occasions, some 8 months apart, the children were evaluated using the Developmental Assessment of Young Children, and their energy intake over the previous day was recorded. Analyses of the dietary and behavioral records indicated that the children's scores on the physical subtest improved significantly. A number of nutrition-development associations were found at follow-up, suggesting that the intervention was successful. Implications of the results for at-risk children are discussed.

Wozniak J, Biederman J, Kwon A *et al.* How cardinal are cardinal symptoms in pediatric bipolar disorder? An examination of clinical correlates. *Biol Psychiatry* 2005; 58(7):583-8. Abstract: BACKGROUND: The main goal of this study was to test whether the hypothesized cardinal symptom of euphoria results in differences in clinical correlates in bipolar youth ascertained with no a priori assumptions about cardinal symptoms. METHODS: Subjects (n = 86) satisfying DSM-IV criteria for bipolar disorder with and without the proposed cardinal symptom of euphoria were compared in their bipolar symptom pattern, functioning and patterns of comorbidity. RESULTS: Among Criterion A (abnormal mood), we found that severe irritability was the predominant abnormal mood rather than euphoria (94% vs. 51%). We also found that among Criterion B items, grandiosity was not uniquely overrepresented in youth with mania, nor did the rate of grandiosity differ whether irritability or irritability and euphoria were the Criterion A mood symptom. Neither symptom profile, patterns of comorbidity nor measures of functioning differed related to the presence or absence of euphoria. CONCLUSIONS: These findings challenge the notion that euphoria represents a cardinal symptom of mania in children. Instead they support the clinical relevance of severe irritability as the most common presentation of mania in the young. They also support the use of unmodified DSM-IV criteria in establishing the diagnosis of mania in pediatric populations.

Wray S, Levy-Milne R. Weight management in childhood: Canadian dietitians' practices. *Can J Diet Pract Res* 2002; 63(3):130-3. Abstract: Canadian dietitians specializing in pediatric practice were surveyed to provide a preliminary profile of the strategies they use to manage overweight youth. The survey was mailed to 298 dietitians belonging to the Dietitians of Canada's (DC) Pediatric Nutrition and Consulting Dietitians' Networks and to the head dietitians in Canadian pediatric hospitals across the country. It was also posted on the DC website and sent by electronic mail. Of the 164 respondents, 65 reported that they provide an intervention program to overweight youth. Growth charts, ideal body weight, and body mass index were mostly used to assess and monitor overweight. However, about 20% of the respondents did not define overweight in their client population. The majority of the clients were girls aged seven to 18. Most respondents used the healthful lifestyle approach via one-on-one consultation, included parents and collaborated with two or more health professionals for the management of these children. As the discussion on best practices for the prevention and treatment of overweight youth continues, we need further evidence to determine what strategies, if any, support positive outcomes in this group.

Wright C, Lee RE. Investigating perinatal death: a review of the options when autopsy consent is refused. *Arch Dis Child Fetal Neonatal Ed* 2004; 89(4):F285-8. Abstract: Autopsy remains the best method of investigating perinatal deaths. Recent years have, however, seen a decline in autopsy rates. This review looks at some of the options available for investigating perinatal deaths when the family decline to give consent for standard autopsy.

Wright DC, Woo WL, Muller RT, Fernandes CB, Kraftcheck ER. An investigation of trauma-centered inpatient treatment for adult survivors of abuse. *Child Abuse Negl* 2003; 27(4):393-406. Abstract: OBJECTIVE: The purpose of this study was to examine a comprehensive inpatient treatment program designed for adult survivors of childhood abuse with posttraumatic stress disorder (PTSD). METHOD: One hundred and thirty-two formerly abused individuals completed clinician-administered and self-administered measures of PTSD symptomatology at admission and discharge. All

participants experienced a range of physical, sexual, and/or emotional abuse as children prior to the age of 17. Approximately one-third of these individuals also completed measures at 3-months postdischarge and 1-year postdischarge. Data were collected using a clinician-administered PTSD measure and self-administered PTSD measure at admission and discharge. On admission, all participants met criteria for a diagnosis of PTSD. RESULTS: Analyses revealed that the program was effective in reducing symptoms from admission to discharge. Additionally, treatment gains were maintained at 1-year postdischarge. CONCLUSION: The findings of this investigation suggest that the current intensive inpatient group treatment program appears to reduce PTSD symptoms effectively for a sample of adult survivors of abuse.

Wright RJ, Steinbach SF. Violence: an unrecognized environmental exposure that may contribute to greater asthma morbidity in high risk inner-city populations. *Environ Health Perspect* 2001; 109(10):1085-9. Abstract: In the United States, rising trends in asthma prevalence and severity, which disproportionately impact minorities and the urban poor, have not been fully explained by traditional physical environmental risk factors. Exigencies of inner-city living can increase psychosocial risk factors (e.g., stress) that confer increased asthma morbidity. In the United States, chronic exposure to violence is a unique stressor existing in many high-risk urban neighborhoods. In this paper, we describe a series of cases that exemplify a temporal association between exposure to violence and the precipitation of asthma exacerbations in four urban pediatric patients. In the first three cases, the nature of the exposure is characterized by the proximity to violence, which ranged from direct victimization (through either the threat of physical assault or actual assault) to learning of the death of a peer. The fourth case characterizes a scenario in which a child was exposed to severe parental conflict (i.e., domestic violence) in the hospital setting. Increasingly, studies have begun to explore the effect of living in a violent environment, with a chronic pervasive atmosphere of fear and the perceived or real threat of violence, on health outcomes in population-based studies. Violence exposure may contribute to environmental demands that tax both the individual and the communities in which they live to impact the inner-city asthma burden. At the individual level, intervention strategies aimed to reduce violence exposure, to reduce stress, or to counsel victims or witnesses to violence may be complementary to more traditional asthma treatment in these populations. Change in policies that address the social, economic, and political factors that contribute to crime and violence in urban America may have broader impact.

Wrisley BA. Reframing the issue: a new child maltreatment prevention message. *N C Med J* 2005; 66(5):367-9.

Wu P, Hoven CW, Liu X, Cohen P, Fuller CJ, Shaffer D. Substance use, suicidal ideation and attempts in children and adolescents. *Suicide Life Threat Behav* 2004; 34(4):408-20. Abstract: Using data from a community sample of youth (N = 1,458; ages 9-17), this study assessed the association between adolescent substance use/abuse and suicidal behaviors. Suicide attempts were strongly associated with alcohol abuse and dependence, followed by frequent cigarette smoking. The associations remained significant even after controlling for depression. The associations between substance use/abuse and suicidal ideation were no longer significant after controlling for depression. These findings highlight the important role that substance use plays in adolescent suicidal behaviors.

Wuest J, Merritt-Gray M, Ford-Gilboe M. Regenerating family: strengthening the emotional health of mothers and children in the context of intimate partner violence. *ANS Adv Nurs Sci* 2004; 27(4):257-74. Abstract: Although concern for their children's well-being is pivotal in mothers' decisions to leave abusive partners, rarely is lone-parent family life after leaving framed as beneficial for family members' emotional health. In this feminist grounded theory study of family health promotion in the aftermath of intimate partner violence, we learned that families strengthen their emotional health by purposefully replacing previously destructive patterns of interaction with predictable, supportive ways of getting along in a process called regenerating family. These findings add to our knowledge of family development and how families promote their health when they have experienced intimate partner violence.

Wyatt J. Medical paternalism and the fetus. *J Med Ethics* 2001; 27 Suppl 2:ii15-20. Notes: GENERAL NOTE: KIE: Wyatt, John GENERAL NOTE: KIE: 14 refs. GENERAL NOTE: KIE: KIE Bib: abortion; fetuses; professional patient relationship Abstract: A number of developments in the medical field have changed the debate about the ethics of abortion. These developments include: advances in fetal physiology, the increase in neonatal intensive care and the survival rates of premature infants. This paper discusses the idea of selective termination and the effects that these decisions have on disabled people of today. It presents a critique of the counselling services that are provided for the parents of a disabled fetus and discusses how this is viewed from a social perspective. The article ends with an argument that the mother deserves to be autonomous in the decision of abortion. The easiest and most fair way to develop her autonomy is to consider the relationship between a professional and a mother as an expert-expert relationship. Here both parties are considered experts in diagnostic information, treatment options, possibilities, and their history, family roots, philosophy and way of life,

respectively.

Wylie JL, Jolly A. Patterns of chlamydia and gonorrhea infection in sexual networks in Manitoba, Canada. *Sex Transm Dis* 2001; 28(1):14-24. Abstract: BACKGROUND: The use of sexual network analysis has the potential to further our understanding of sexually transmitted disease (STD) epidemics and contribute to the development of more effective targeted control strategies. GOAL: To use sexual network analysis to study transmission patterns of chlamydia and gonorrhea in Manitoba, Canada. STUDY DESIGN: Routinely collected case/contact information gathered by public health nurses was used to construct the sexual network. RESULTS: Components within the sexual network ranged in size from 2 to 82 people. Two types of components, designated radial and linear, were described. Large linear components resembled the theoretical structure of STD core groups. Geographic analysis of the largest components demonstrated the potential for STD transmission between isolated rural communities and within different areas of an urban center. CONCLUSIONS: The application of sexual network analysis on a provincial basis demonstrated the importance of a centralized, coordinated approach to STD control. The analysis highlights the need for a greater understanding of the causative factors promoting the formation of different component types, the homogeneity and heterogeneity of behaviors within and between components, and the temporal stability of these patterns.

Yaghmai R, Kashani AH, Geraghty MT *et al.* Progressive cerebral edema associated with high methionine levels and betaine therapy in a patient with cystathionine beta-synthase (CBS) deficiency. *Am J Med Genet* 2002; 108(1):57-63. Abstract: Cystathionine beta-synthase (CBS) deficiency, the most common form of homocystinuria, is an autosomal recessive inborn error of homocysteine metabolism. Treatment of B6-nonresponsive patients centers on lowering homocysteine and its disulfide derivatives (tHcy) by adherence to a methionine-restricted diet. However, lifelong dietary control is difficult. Betaine supplementation is used extensively in CBS-deficient patients to lower plasma tHcy. With betaine therapy, methionine levels increase over baseline, but usually remain below 1,500 micromol/L, and these levels have not been associated with adverse effects. We report a child with B6-nonresponsive CBS deficiency and dietary noncompliance whose methionine levels reached 3,000 micromol/L on betaine, and who subsequently developed massive cerebral edema without evidence of thrombosis. We investigated the etiology by determining methionine and betaine metabolites in our patient, and several possible mechanisms for her unusual response to betaine are discussed. We conclude that the cerebral edema was most likely precipitated by the betaine

therapy, although the exact mechanism is uncertain. This case cautions physicians to monitor methionine levels in CBS-deficient patients on betaine and to consider betaine as an adjunct, not an alternative, to dietary control.

Yamada H. Japanese mothers' views of young children's areas of personal discretion. *Child Dev* 2004; 75(1):164-79.

Abstract: Sixty-four Japanese mothers of 3- to 6-year-olds were interviewed concerning their conceptions of children's areas of personal control. Mothers granted children choices regarding recreational activities, clothes, and friends to foster autonomy and competence, but they set limits around daily routines, recreational activities, and interpersonal confrontation based on moral, conventional, and prudential concerns. Mothers believed in reaffirming children's personal boundaries when children failed to follow through with their initial decisions. Mothers experienced conflict with children around daily routines and recreational activities and used various resolution strategies. Mothers perceived child resistance as egocentric whereas fewer considered it as establishing personal boundaries. Some age and gender differences were observed. Results supported the heterogeneity of social judgments and practices of individuals within cultures.

Yamawaki S. [Early childhood trauma and stress-related psychiatric disorders: neuroscience perspective]. *Seishin Shinkeigaku Zasshi* 2005; 107(5):506-13.

Abstract: Morphometric studies using magnetic resonance imaging have reported smaller than normal volumes of the hippocampus in stress-related psychiatric disorders such as major depression, post-traumatic stress disorders (PTSD) etc... On the other hand, epidemiological studies have suggested that early childhood trauma including child abuse and sexual abuse is associated with markedly elevated rates of major depression and PTSD. Psychoanalyst and child psychiatrists have reported that mother-child relationship and fostering environment in early childhood strongly affect the later mental development and increase the prevalence rate of various psychiatric disorders, but its biological mechanism has not been elucidated. Recent progress of neuroscience research has brought a possibility to elucidate molecular biological mechanism of this developmental psychological issue. The author reviews recent neuroscience researches focused on the effect of early childhood trauma on the stress vulnerability and the pathogenesis of stress-related psychiatric disorders.

Yancey AK, Siegel JM, McDaniel KL. Role models, ethnic identity, and health-risk behaviors in urban adolescents. *Arch Pediatr Adolesc Med* 2002; 156(1):55-61.

Abstract: BACKGROUND: The assumption that role models or mentors constructively influence adolescent

psychological functioning has prompted societal investment in mentoring programs. However, there has been little empirical evaluation of the relationship between role model or mentor characteristics and health behaviors. **OBJECTIVES:** To describe role model selection in urban adolescents and examine the relationships between role model characteristics, psychosocial functioning, and health-risk behaviors. **DESIGN:** Cross-sectional survey. **PARTICIPANTS:** A population-based, multiethnic sample of Los Angeles County adolescents aged 12 to 17 years was generated from a 3-stage, area-probability sampling frame. Of 877 adolescents identified, 749 are included in this analysis. **METHODS:** In-person, in-home interviews were conducted. **MAIN OUTCOME MEASURES:** Substance use, academic performance, and self-perception (measures of ethnic identity and self-esteem). Ethnic identity was measured by an adaptation of a scale developed by Phinney (*J Adolesc Res*. 1992;7:156-176) to assess commonalities across ethnic groups. **RESULTS:** Fifty-six percent of adolescents identified a role model. Higher levels of ethnic identity were associated with moving from identifying no role model to identifying a figure primarily available through the media to identifying a known individual, familial or nonfamilial ( $P < .001$ ). Having a role model, particularly an individual known to the adolescent, was also associated with higher self-esteem ( $P < .001$ ) and higher grades ( $P < .05$ ). For white males without custodial fathers, having a role model was associated with decreased substance use ( $P < .05$ ). **CONCLUSION:** Role model selection is associated with protective psychosocial characteristics.

Yang JW, Kuppermann N, Rosas A. Child abuse presenting as pseudorenal failure with a history of a bicycle fall. *Pediatr Emerg Care* 2002; 18(2):91-2.

Yates A. Biologic perspective on early erotic development. *Child Adolesc Psychiatr Clin N Am* 2004; 13(3):479-96, vi. **Abstract:** Neurobiologic researchers can understand children's sexuality in less moral and more biologic terms. Genetically programmed levels of neurotransmitters and hormones establish a baseline trajectory of erotic interest and activity across the lifespan. Environmental influences also contribute. Intense early stimulation can affect the brain and create a condition of hyper eroticism, whereas too little stimulation can limit the ability to bond and impair the sexual response. Children who are erotically challenged or challenging are viewed correctly as having a brain imbalance, rather than as victims or as being morally deficient. This should pave the way for more humane, objective, and effective interventions.

Yazicioglu M, Asan A, Ones U *et al*. Indoor airborne fungal spores and home characteristics in asthmatic children from Edirne region of Turkey. *Allergol Immunopathol*

(Madr) 2004; 32(4):197-203. **Abstract:** **BACKGROUND:** The contribution of indoor fungal exposure to childhood asthma is not completely clear. **OBJECTIVE:** To investigate airborne fungal flora within the homes of asthmatic and control children, and to assess the influence of housing characteristics regarding indoor fungi. **METHODS:** Forty-seven atopic asthmatic and 23 nonatopic control children were studied. Allergen sensitivity was determined by skin prick tests. A thorough assessment, using a questionnaire and inspection surveys, was carried out. Home visits were made between October 2000 and February 2001. Samples of airborne fungal spores were collected from four rooms by the "open Petri dish" method. Indoor temperature and humidity were measured. **RESULTS:** The total indoor fungal colony counts from the living rooms and bedrooms were significantly higher in the asthma group than in controls ( $p = .012$  and  $p = .003$ , respectively). The most commonly isolated genus was *Cladosporium*. Twelve of the asthmatic patients (25.53 %) were found to be sensitive to fungal allergens. The factors found to be associated with indoor fungal growth in logistic regression were visible fungal patches in the bathrooms [(odds ratio (OR) = 5.75; 95 % CI 1.19 to 27.70)], and the age of the house [OR = 4.24; 95 % CI 1.34 to 13.45]. Total fungal colony numbers did not correlate with indoor temperature or humidity. **CONCLUSION:** Fungal colony numbers were higher in the homes of asthmatic children than in those of controls. Therefore, indoor fungal exposure may contribute to childhood asthma. Bathrooms were the main source of fungal propagules. Old houses were more prone to fungal growth.

Ybarra ML, Mitchell KJ. Exposure to internet pornography among children and adolescents: a national survey. *Cyberpsychol Behav* 2005; 8(5):473-86. **Abstract:** Estimates suggest that up to 90% or more youth between 12 and 18 years have access to the Internet. Concern has been raised that this increased accessibility may lead to a rise in pornography seeking among children and adolescents, with potentially serious ramifications for child and adolescent sexual development. Using data from the Youth Internet Safety Survey, a nationally representative, cross-sectional telephone survey of 1501 children and adolescents (ages 10-17 years), characteristics associated with self-reported pornography seeking behavior, both on the Internet and using traditional methods (e.g., magazines), are identified. Seekers of pornography, both online and offline, are significantly more likely to be male, with only 5% of self-identified seekers being female. The vast majority (87%) of youth who report looking for sexual images online are 14 years of age or older, when it is developmentally appropriate to be sexually curious. Children under the age of 14 who have intentionally looked at pornography are more likely to report traditional exposures, such as magazines or movies. Concerns

about a large group of young children exposing themselves to pornography on the Internet may be overstated. Those who report intentional exposure to pornography, irrespective of source, are significantly more likely to cross-sectionally report delinquent behavior and substance use in the previous year. Further, online seekers versus offline seekers are more likely to report clinical features associated with depression and lower levels of emotional bonding with their caregiver. Results of the current investigation raise important questions for further inquiry. Findings from these cross-sectional data provide justification for longitudinal studies aimed at parsing out temporal sequencing of psychosocial experiences.

Ye DQ, Zhu JM, Zhang YQ *et al.* [A survey on violence among primary and secondary school students in Hefei city]. *Zhonghua Liu Xing Bing Xue Za Zhi* 2004; 25(1):6-8.

Abstract: **OBJECTIVE:** To explore the features of violence among primary and secondary school students in Hefei, and to set up intervention measures for violence prevention. **METHODS:** Four schools in Hefei were randomly sampled in the study. A total of 3064 students completed a questionnaire. **RESULTS:** 16.22% of the pupils reported having suffered from violence at least once every month. The rate was higher in boys than that in girls's ( $\chi^2 = 25.13, P = 0.000$ ). The major assaulters were from classmates (45.80%), with hand beating (37.42%), insulting (31.21%), threatening (20.88%), and 10.49% using sticks and sharp weapons. Most violence occurred at school (46.08%), followed by at home (28.41%) and outside of schools (25.51%), with significant difference ( $P = 0.000$ ). As a result, 3.33% ended up with fractures, and 0.51% with disability. 97 pupils reported having assaulted others frequently (3.21%). Being irritated (47.38%) was the major reason for the violence to occur. **CONCLUSION:** Violence among primary and secondary school students in Hefei city was serious that called for targeted education be strengthened and school environment be improved.

Yeole BB, Kumar AV, Kurkure A, Sunny L. Population-based survival from cancers of breast, cervix and ovary in women in Mumbai, India. *Asian Pac J Cancer Prev* 2004; 5(3):308-15.

Abstract: **BACKGROUND:** Breast, cervix and ovarian cancers contribute more than 45% of the total in women in Mumbai and survival proportions for these neoplasms are very high in most developed populations in the World. The authors here report and discuss the population-based survival for these cancers in Mumbai, India. **METHODS:** Follow-up information on 4865 cancers of breast, cervix and ovary, registered in the Mumbai Population Based Cancer Registry for the period 1992-1994 was obtained by a variety of methods, including matching with death certificates from the Mumbai vital statistics registration system, postal/telephone enquiries, home visits and scrutiny of

medical records. The survival for each case was determined as the duration between the date of diagnosis and date of death, date of loss to follow-up or the closing date of the study (December 31(st), 1999). Cumulative observed and relative survival was calculated by the Hakulinen Method. For comparison of results with other populations, age-standardized relative survival (ASRS) was calculated by directly standardizing age specific relative survival to the specific age distributions of the estimated global incidence of major cancers in 1985. The log rank test was used in univariate analysis to identify the potentially important prognostic variables. The variables showing statistical significance in univariate analysis were introduced stepwise into a Cox Regression model to identify the independent predictors of survival. **RESULTS:** The 5-year relative survival rates were 46.2% for breast, 47.7% for the cervix and 25.4% for the ovary. Higher survival was observed for those younger than 35 years for all these three sites. For each, survival declined with advancing age. Single patients who remained unmarried had better survival. For all sites Muslims had a better and Christians a lower survival as compared to Hindus. Education did not appear to be of significance. Survival decreased rapidly with advancing clinical extent of disease for all sites. With localized cancer, 5-year rates ranged from 54.7% to 69.3%, for regional spread 20.4% to 41.6% and distant metastasis not a single site recorded more than 5%. On multivariate analysis, age and extent of disease emerged as independent predictors of survival for all the sites. **CONCLUSION:** All the sites included in the study demonstrated moderate survival rates with significant variation. Comparison with other populations revealed lower survival rates as compared to developed countries, particularly for breast and ovary. In Indian populations survival proportions did not show much variation for these cancers. Early detection and treatment are clearly important factors to reduce the mortality from these cancers.

Yeole BB, Sunny L, Swaminathan R, Sankaranarayanan R, Parkin DM. Population-based survival from colorectal cancer in Mumbai, (Bombay) India. *Eur J Cancer* 2001; 37(11):1402-8.

Abstract: Survival estimates of patients registered by population-based cancer registries reflect the average prognosis from a given cancer as they are based on unselected patients with a wide range of natural histories and treatment patterns. In this paper, we report the survival experience of colorectal cancer patients in Mumbai (Bombay), India. Follow-up information on 1642 colorectal cancer patients registered by the Bombay Population-based Cancer Registry for the period 1987-1991 was obtained by matching with death certificates from the Bombay vital statistics registration system, postal/telephone enquiries, home visits and scrutiny of medical records. Cumulative observed and relative survival proportions

were calculated by Hakulinen's method. For comparison of results with other populations, age-standardised relative survival (ASRS) was calculated by directly standardising age-specific relative survival to the specific age distributions of the world standard cancer patient population in 1985. The log-rank test was used to identify the potential prognostic variables which were introduced step-wise into a Cox regression model to identify the independent predictors of survival. The 5-year relative survival was 36.6% for colon and 42.2% for rectal cancer. Age, site of cancer and clinical stage of disease emerged as independent predictors of survival. Age-specific 5-year relative survival declined with advancing age. Survival at 5 years was 61.2% for localised colon cancer; 31.9% for regional and 9.0% for distant metastatic disease. These were 65.7, 25.6 and 4.3%, respectively for rectal cancers. Comparison of the results with other populations revealed significant variations, which seem to be related to differences in detection and treatment. The prognosis from colorectal cancer in Mumbai and developing countries, may be further improved through early detection linked with treatment.

Yeung EK, Hsiao TC, Chiang HK, Lin CW. Prediction of burn healing time using artificial neural networks and reflectance spectrometer. *Burns* 2005; 31(4):415-20. Abstract: BACKGROUND: Burn depth assessment is important as early excision and grafting is the treatment of choice for deep dermal burn. Inaccurate assessment causes prolonged hospital stay, increased medical expenses and morbidity. Based on reflected burn spectra, we have developed an artificial neural network to predict the burn healing time. PURPOSE: Our study is to develop a non-invasive objective method to predict burn-healing time. METHODS AND MATERIALS: Burns less than 20% TBSA was included. Burn spectra taken on the third postburn day using reflectance spectrometer were analyzed by an artificial neural network system. RESULTS: Forty-one spectra were collected. With the newly developed method, the predictive accuracy of burns healed in less than 14 days was 96%, and that in more than 14 days was 75%. CONCLUSIONS: Using reflectance spectrometer, we have developed an artificial neural network to determine the burn healing time with 86% overall predictive accuracy.

Yeung WJ, Linver MR, Brooks-Gunn J. How money matters for young children's development: parental investment and family processes. *Child Dev* 2002; 73(6):1861-79. Abstract: This study used data from the Panel Study of Income Dynamics and its 1997 Child Development Supplement to examine how family income matters for young children's development. The sample included 753 children who were between ages 3 and 5 years in 1997. Two sets of mediating factors were examined that reflect two dominating views in the literature: (1) the investment perspective, and (2) the family process perspective. The study examined how two measures of

income (stability and level) were associated with preschool children's developmental outcomes (Woodcock-Johnson [W-J] Achievement Test scores and the Behavior Problem Index [BPI]) through investment and family process pathways. Results supported the hypothesis that distinct mediating mechanisms operate on the association between income and different child outcomes. Much of the association between income and children's W-J scores was mediated by the family's ability to invest in providing a stimulating learning environment. In contrast, family income was associated with children's BPI scores primarily through maternal emotional distress and parenting practices. Level of income was associated with W-J letter-word scores and income stability was associated with W-J applied problem scores and BPI, even after all controls were included in the models.

Yin Z, Hanes J Jr, Moore JB, Humbles P, Barbeau P, Gutin B. An after-school physical activity program for obesity prevention in children: the Medical College of Georgia FitKid Project. *Eval Health Prof* 2005; 28(1):67-89.

Abstract: This article describes the process of setting up a 3-year, school-based after-school physical activity intervention in elementary schools. The primary aim of the study is to determine whether adiposity and fitness will improve in children who are exposed to a fitogenic versus an obesogenic environment. Eighteen schools were randomized to the control (obesogenic) or intervention (fitogenic) group. The study design, program components, and evaluation of the intervention are described in detail. The intervention consists of (a) academic enrichment, (b) a healthy snack, and (c) physical activity in a mastery-oriented environment. Successful implementation would show the feasibility of schools' being able to provide a fitogenic environment. Significant differences between the groups would provide evidence that a fitogenic environment after school has positive health benefits. If feasibility and efficacy are demonstrated, implementing an after-school program like this one in elementary schools could play a major role in preventing and reducing childhood obesity.

Yip R. Iron supplementation: country level experiences and lessons learned. *J Nutr* 2002; 132(4 Suppl):859S-61S.

Abstract: Iron supplementation is a commonly used strategy to meet the increased requirements of at-risk groups, such as women of childbearing age, especially during pregnancy. Other at-risk groups for which iron supplementation may be appropriate include infants, young children, adolescents and the elderly. There is a need to consider iron supplementation as part of a comprehensive strategy for the prevention of iron deficiency, and not just as a treatment for anemia that is stopped as soon as clinical improvement is noted. Experience in developing countries indicates that often the poorest women with the most deficient intakes are

the least likely to receive iron supplements during pregnancy. Providing supplements to women during antenatal care visits is useful but often inadequate, so other delivery channels must also be explored, including private sector markets and community networks. Communication efforts must be expanded to increase understanding of the importance of taking supplements and to address any fears or misconceptions relating to supplementation. Overall, we must increase the capacity of individuals and communities to define, analyze and act to address their own health needs.

Yonge O, Haase M. Munchausen syndrome and Munchausen syndrome by proxy in a student nurse. *Nurse Educ* 2004; 29(4):166-9. Abstract: Most faculty are not prepared for the possibility of encountering Munchausen syndrome (MS) in nursing students and Munchausen syndrome by proxy (MSP) in nursing students' children. When confronted with MS or MSP, their first reaction is often hostility coupled with a sense of betrayal. Given that individuals with this condition are attracted to helping professions, the authors describe both conditions in a case in which a nursing student presented with MS and the student's daughter was a victim of MSP. The focus is on protection of any children and the public, psychiatric treatment for the offender, and assistance for faculty.

Yordanova J, Kolev V, Heinrich H, Woerner W, Banaschewski T, Rothenberger A. Developmental event-related gamma oscillations: effects of auditory attention. *Eur J Neurosci* 2002; 16(11):2214-24. Abstract: This study describes maturational changes in topographical patterns, stability, and functional reactivity of auditory gamma band (31-63 Hz) responses (GBRs) as brain electrical correlates relevant for cognitive development during childhood. GBRs of 114 healthy children from 9 to 16 years were elicited in an auditory focused attention task requiring motor responding to targets, and analyzed by means of the wavelet transform (WT). The effects of age and task variables (attended side and stimulus type relevance) were examined for GBR power and phase-locking within 120 ms after stimulation. Similar to the spontaneous gamma band power, the power and phase-synchronization of GBRs did not depend on the age. However, the functional reactivity of GBRs at specific locations changed in the course of development. In 9-12-year-old children, GBRs at frontal locations were larger and better synchronized to target than to nontarget stimulus type, and were larger over the left hemisphere (contralateral to the responding hand), thus manifesting sensitivity to external stimulus features and motor task. In 13-16-year-old adolescents, GBRs at parietal sites were enhanced by active attending to the side of stimulation, thus being associated with a maintenance of attentional focus to stimulus location. The results indicate that (i) specific aspects of task-

stimulus processing engage distinct spatially localized gamma networks at functionally relevant areas, and (ii) the neuronal substrates of gamma band networks and the ability to synchronize them in relation to task-specific processes are available in all age groups from 9 to 16 years. However, the mode and efficiency with which gamma networks can be entrained depends on the age. This age-dependent reactivity of GBRs to different task variables may reflect a transition in processing strategies emerging at approximately 12-13 years in relation to the maturation of cognitive and executive brain functions.

Yorke S. Brassed off with knee-jerk reactions. *Nurs Times* 2001; 97(32):21.

Yost NP, Bloom SL, McIntire DD, Leveno KJ. A prospective observational study of domestic violence during pregnancy. *Obstet Gynecol* 2005; 106(1):61-5. Abstract: OBJECTIVE: To assess whether women reporting domestic violence are at increased risk for adverse pregnancy outcomes. METHODS: A screening questionnaire, previously validated for the identification of female victims of domestic violence, was offered to women presenting to our Labor and Delivery Unit. The survey prompted women to indicate whether her partner or family member physically hurt her, insulted or talked down to her, threatened her with harm, or screamed or cursed at her. The primary study outcome was to detect a 3-fold increase in low birth weight infants (< or = 2,500 g) in women reporting physical abuse, compared with those not reporting domestic violence. RESULTS: A total of 16,041 women were approached to be interviewed. Of these, 949 (6%) women responded affirmatively to one or more of the survey questions, and another 94 (0.6%) declined to be interviewed. The incidence of low birth weight infants was significantly increased in women who reported verbal abuse, compared with the no-abuse group (7.6% versus 5.1%, respectively,  $P = .002$ ). Physical abuse was associated with an increased risk of neonatal death (1.5% versus 0.2%,  $P = .004$ ). Interestingly, women who declined to be interviewed had significantly increased rates of low birth weight infants (12.8% versus 5.1%,  $P < .001$ ), preterm birth at 32 weeks of gestation or less (5.3% versus 1.2%,  $P = .002$ ), placental abruptions (2.1% versus 0.2%,  $P < .001$ ), and neonatal intensive care admissions (7.4% versus 2.2%,  $P = .008$ ) when compared with women in the no-abuse group, respectively. CONCLUSION: Women who declined to be surveyed regarding domestic violence were at increased risk for adverse pregnancy outcome. LEVEL OF EVIDENCE: II-2.

Youd J. Lost generation? *Emerg Nurse* 2005; 12(9):15-7.

Young B, Dixon-Woods M, Findlay M, Heney D. Parenting in a crisis: conceptualising mothers of children with cancer. *Soc Sci Med* 2002; 55(10):1835-47.

Abstract: Much research on the experiences of parents of children with cancer has been conducted within a discourse of psycho-pathology, or has tended to see parents mostly as a proxy source of information on the well-being of their children. Using empirical data from semi-structured interviews with 20 mothers of a child with cancer, in one area of the UK, we draw on sociological literatures on motherhood, childhood, caring, and chronic illness to suggest a more helpful and informative way of understanding their experiences. We suggest that mothers, although not ill themselves, experience many of the consequences of chronic illness. Biographical disruption begins for them when they first notice something wrong with their child, and intensifies with diagnosis, altering their sense of self and their social identity. The diagnosis brings with it a set of new responsibilities and role expectations, including an obligation of 'proximity'-being physically close to their child at all times to provide 'comfort' and 'keep-watch'. For mothers, caring evokes an intense emotional interdependence with their sick child, and involves a range of technical tasks and emotional work, including acting as 'brokers' of information for their child and managing their cooperation with treatment. Managing these obligations was achieved at high cost to the mothers themselves, and resulted in severe role strain by compromising their ability to function in other roles, including their role as the mother of their other children. Against the backdrop of a severe and life-threatening illness, everyday concerns about their child's diet or appropriate discipline take on a new significance and carry a heightened potential for generating conflict and distress for mothers. In presenting their accounts, mothers draw on prevailing cultural discourses about motherhood, childhood and cancer, and these clearly influence the context in which they care for their child, and shape their reflexive constructions of their experiences. Caring for a child with cancer had many adverse implications for the quality of life of the women we studied. Mothers of a child with cancer warrant study in their own right, and such study benefits from interpretive perspectives.

Young S, Heptinstall E, Sonuga-Barke EJ, Chadwick O, Taylor E. The adolescent outcome of hyperactive girls: self-report of psychosocial status. *J Child Psychol Psychiatry* 2005; 46(3):255-62. Abstract: BACKGROUND: The aim of the study was to clarify the developmental risk associated with hyperactive behaviour in girls in a longitudinal epidemiological design. METHODS: This was investigated in a follow-up study of girls who were identified by parent and teacher ratings in a large community survey of 6- and 7-year-olds as showing pervasive hyperactivity or conduct problems or the comorbid mixture of both problems or neither problem. They were later investigated, at the age of 14 to 16 years, with a detailed self-report interview technique. RESULTS: Hyperactivity was a risk factor for later

development, even allowing for the coexistence of conduct problems. Hyperactivity predicted academic problems and interpersonal relationship problems. Relationships with parents, by contrast, were not portrayed to be as problematic as relationships with peers and the opposite sex. Their psychological, social and occupational functioning was objectively rated to be more deviant and their self-report showed them to be more ambivalent about their future. There was a trend for hyperactivity to be self-reported as a risk for the development of continuing symptomatology but neither hyperactivity nor conduct problems were self-reported to be a risk for antisocial behaviour, substance misuse or low self-esteem in adolescence. However, they were at risk for the development of state anxiety. CONCLUSIONS: The results suggested girls' pattern of functioning may differ from that of boys because girls self-report a more pervasive range of social dysfunction than that previously reported in boys.

Young SE, Smolen A, Corley RP *et al.* Dopamine transporter polymorphism associated with externalizing behavior problems in children. *Am J Med Genet* 2002; 114(2):144-9.

Abstract: Early childhood externalizing behavior is a stable and heritable pattern of aggressive and delinquent behavior that often leads to the development of serious psychiatric disorders such as conduct disorder and attention deficit hyperactivity disorder. We examined the relationship between parent reported externalizing behavior (assessed at ages 4, 7, and 9 years) and the VNTR polymorphism of the 3' untranslated region of SLC6A3 (DAT1) in a community sample of 790 children ascertained as part of our longitudinal twin and adoption studies. We applied the sibling-based methodology developed by Fulker *et al.* [1999: *Am J Hum Genet* 64:259-267] for estimating allelic association with quantitative traits, while controlling for population stratification. An extension of these methods allowed for the inclusion of monozygotic twins, dizygotic twins, siblings, and singletons. We have demonstrated that the 9-repeat variant of the DAT1 is a significant risk allele for externalizing behavior at ages 4 ( $P=0.001$ ) and 7 years ( $P=0.02$ ). Although the effect size was negligible at age 9 ( $P=0.92$ ), a formal test of the developmental decrease in effect across the three ages was non-significant ( $P=0.70$ ).

Youngstrom E, Weist MD, Albus KE. Exploring violence exposure, stress, protective factors and behavioral problems among inner-city youth. *Am J Community Psychol* 2003; 32(1-2):115-29.

Abstract: This study examined relationships between violence exposure, other stressors, family support, and self-concept on self-reported behavioral problems among 320 urban adolescents (aged 11-18) referred for mental health treatment. Overall, participants reported high levels of violence exposure, with a median of six past encounters with violence as a witness, victim, or

through the experiences of associates. All forms of violence exposure (witnessing, being a victim, knowing of victims) were correlated with internalizing and externalizing behavioral problems for males and females. Total violence exposure predicted behavioral problems among participants, even after controlling for the effects of other risk, demographic and protective factors. Family support and self-concept moderated the influence of life stress and cumulative risk on problem behavior outcomes, but these protective variables did not significantly moderate violence exposure.

Yozwiak JA, Golding JM, Marsil DF. The impact of type of out-of-court disclosure in a child sexual assault trial. *Child Maltreat* 2004; 9(3):325-34. Abstract: This study investigated the impact of type of out-of-court disclosure in a child sexual assault case involving a 6-year-old alleged victim. Community participants read a fictional criminal trial summary of a child sexual assault case in which the alleged victim's out-of-court disclosure of the assault was: (a) complete on two occasions or (b) incomplete at first, but later included the full account of the incident. The results showed that there were more guilty verdicts, higher ratings of the defendant's guilt, and greater belief of the alleged victim when there was full disclosure on two occasions compared to when there was a delay in full disclosure. These results are discussed in terms of the impact the nature of out-of-court disclosure can have when a child testifies in a sexual assault case.

Ytterstad B. The Harstad Injury Prevention Study. A decade of community-based traffic injury prevention with emphasis on children. Postal dissemination of local injury data can be effective. *Int J Circumpolar Health* 2003; 62(1):61-74. Abstract: OBJECTIVES: To evaluate the outcome of a community-based program for reducing traffic injury rates with special focus on children and to assess the impact of a Traffic Injury Report (TIR) in terms of awareness and attitudes about safety issues. SETTING: The Norwegian cities Harstad (23 000) and Trondheim (140 000), during ten years. METHODS: The outcome was evaluated using hospital-based injury recording. Sustainability of the prevention program was promoted by disseminating information on the community's traffic injury profile. Reports containing information about traffic injuries were distributed quarterly to all Harstad households, containing victim stories and statistics on medical data and the location of the accidents. The impact of the reports was evaluated, using a questionnaire mailed to persons 18-80 years old. RESULTS: From the first two years (mean rate 116.1/10,000 person years), to last two years, a significant 59% [confidence interval (CI): 42% to 71%] reduction of traffic injury rates was observed for Harstad children. Overall rates for all ages decreased 37% [CI:47% to 24%] in Harstad increased by 3% [CI:-4% to 10%] in Trondheim (reference city). Significantly higher scores were found in Harstad

compared to Trondheim concerning the awareness of, and positive attitudes towards, safety issues (e.g. alcohol and driving, speeding and children's safety in traffic). 56.0% of respondents in Harstad reported having acquired information, or good advice, about traffic safety from the reports. CONCLUSIONS: Traffic injuries in children can be prevented by community-based interventions. Distributing written information may enhance the program's sustainability.

Ytterstad B, Norheim AJ. The epidemiology of injuries in Svalbard compared with Harstad. *Int J Circumpolar Health* 2001; 60(2):184-95. Abstract: STUDY OBJECTIVE: To survey all injuries treated in Longyearbyen hospital, Svalbard and to describe the injury epidemiology for Svalbard (residents and visitors), comparing it with Harstad. SETTING: The Norwegian arctic archipelago, Svalbard and the mainland city Harstad during three years from 8 March 1997. PARTICIPANTS: The person years of the study were 4211 for Svalbard residents and 69,014 for Harstad. MEASUREMENTS AND MAIN RESULTS: The variables followed the Nordic system. Of 630 recorded injuries, 107 were snowmobile related. Crude injury rates (per 1000 person years) [corrected] for Svalbard residents were for men 100.9 and for women 76.3. Corresponding rates were not significantly higher for men in Harstad (115.4,  $p = 0.19$ ) and for women (80.1,  $p = 0.56$ ). Home injuries were more prevalent in Harstad (30.5%) compared to Svalbard residents (13.1%,  $p < 0.001$ ) and visitors (8.9%,  $p < 0.001$ ). Work and leisure related injuries were more prevalent for Svalbard visitors (38.8% and 48.7%) and residents (27.2% and 41.9%) compared to Harstad (13.2% and 34.8%) (both  $p < 0.001$ ). 43.5% of Svalbard visitors sustained work related injuries at sea. These injuries had higher AIS (abbreviated injury scale) mean score (1.83) than visitors' work injuries occurring on land (1.41) ( $p < 0.05$ ) and residents' work injuries (1.29) ( $p < 0.001$ ). Harstad had lowest AIS score for work related injuries (1.24). The violence rate (per 1000 person years) was 0.9 for Svalbard residents, less than a third of the Harstad rate ( $p < 0.02$ ). There was one Svalbard resident fatality (drowning).

Yu BP, Chung HY. Stress resistance by caloric restriction for longevity. *Ann N Y Acad Sci* 2001; 928:39-47. Abstract: Hardly an aspect of aging is more important than an organism's ability to withstand stress or to resist both internally and externally imposed insults. We know that as organisms lose their ability to resist these insults, aged organisms suffer more than the young. Therefore, a prime strategy for an organism's survival has been the evolutionarily adapted defense systems that guard against insult. For better survivability, an organism's defense system must be maximized to its full effect through well-coordinated networks of diverse biologically responsive elements. Although terms like stress, resistance, and adaptability

have long been used in biology, they remain mechanistically and quantitatively poorly defined. In a gerontological context, stress resistance or susceptibility are often discussed in association with an organism's vulnerability to disease and age-related damage. However, to date, there is no clear molecular delineation of cellular and molecular mechanisms for such complex biological phenomena. The life-prolonging action of caloric restriction (CR) seems to offer an excellent opportunity for investigating the interrelationship between stress and the aging process. As an omnipotent intervention, CR provides a unique opportunity to probe the organism's ability to withstand age-related stress as a survival strategy. In this context, the antiaging action of CR can be viewed as "nutritional stress," because the organism's reduced caloric intake seems to be a stimulatory metabolic response for survivability. Recent gerontologic research has provided sufficient experimental data supporting this antiaging property of CR, of which several pertinent, key examples are discussed below.

Yu J, Fairbank JC, Roberts S, Urban JP. The elastic fiber network of the annulus fibrosus of the normal and scoliotic human intervertebral disc. *Spine* 2005; 30(16):1815-20.

**Abstract:** **STUDY DESIGN:** Immunohistochemical study of elastic fibers in human intervertebral discs (IVD) collected at surgery from patients with scoliosis. **OBJECTIVES:** To compare the elastic fiber network in scoliotic discs (idiopathic scoliosis or neuromuscular scoliosis) to that of control (normal) discs. To study whether the change in elastic fiber organization could contribute to the progression of spinal deformity. **SUMMARY OF BACKGROUND DATA:** Elastin and elastic fibers have been identified previously in human IVD but were believed to contribute little to the tissue's mechanical properties. However, a recent immunohistochemical study has revealed an abundant and organized elastic fiber network in bovine IVD, indicating that elastic fibers could play an important mechanical role. This article reports the organization of elastic fibers in human IVD and the changes of elastic fiber organization in scoliosis. **METHODS:** Intact wedges of IVD were obtained from patients undergoing surgery for scoliosis (aged 12-22 years). Control discs were obtained from a patient (aged 12 years) with a spinal tumor and a trauma patient (aged 17 years). The discs were dissected to give radial slices and were snap frozen. Frozen sections were cut and digested with hyaluronidase to remove glycosaminoglycans. Micrographs of the sections were examined by polarized light to visualize collagen organization. The elastic fiber network was visualized immunohistochemically or by histochemical staining with orcein. **RESULTS:** A highly organized elastic fiber network, similar to that described in bovine discs, was revealed in the control human discs. In the annulus fibrosus of control discs, dense elastic fibers were located between adjacent lamellae, with fibers also

present within individual lamellae. Elastic fibers appeared to be long (>200 microm) and straight in outer annulus, whereas in inner annulus, they nearly ran parallel to each other and at an angle of approximately 60 degrees or 120 degrees to those in adjacent lamellae. However, in scoliotic discs, elastic fibers were sparse, and the collagen and elastic fiber networks were disorganized with loss of lamellar structure. Cell clusters, one of typical degenerative feature, were seen in scoliotic discs but not in age-matched control discs. **CONCLUSIONS:** Our results reveal an abundant and organized network of elastic fibers in the adolescent (12 and 17-year-olds) human IVD, and suggest that elastic fiber network plays a significant biomechanical role. This network is sparse and disrupted in scoliotic discs, and could be involved in the progression of the spinal deformity.

Zaba R, Bukartyk-Rusek B. [School hygiene in the past, present and future--in the opinion of the Inspector of Pediatrics and School Medicine and member of the European Society for Social Pediatrics (ESSOP)]. *Wiad Lek* 2002; 55 Suppl 1:615-9. **Abstract:** Yesterday. School hygiene acted in a clear way. Physician, pediatrician, nurse and hygienist were employed at school and were responsible for carrying out periodic examination, vaccination of school children and youth. They also supervised groups of children with posture defects, obesity, underweight, circulatory system and respiratory tract (asthma, anaphylaxis), diseases nervous system disorders and also propagated health education at school. Inspector of Pediatrics and School Medicine was in charge of School Medical Care. Today. Reform of the Public Health System. Medical examination and services have their value in money. A school physician, some hygienists and school nurses have been dismissed to decrease the financial costs of school hygiene. All medical services must be bought by the National Health Service. Public and private medical services at doctors and nurses are organized at schools. Each service performs examinations, vaccinations bought by the National Health Service or parents. A pupil is a subject of buying medical services. He may be vaccinated by a nurse but a medical examination must be either bought or performed by home doctor. The supervision of school children with different illnesses is not conducted by a school doctor. At present all the threats of contemporary world such as alcohol, tobacco, drug addiction, nervous system illnesses and allergies which are destructive for youth start when they are teenagers. School is an important place for carrying out on a large scale prophylactic services with medical teams of paediatricians, rehabilitation specialists and psychologists. Tomorrow. School Hygiene at School. Not at home doctor's. Recommendations, Daily Hygiene: personal, oral, food mental... Hygiene of studying, rest and daily effort. Struggle with mass media, alcohol, drug, Internet, Computer addiction, violence, stupidity and poverty.

School Hygiene should be adjusted to youth's health needs in accordance with the recommendations of European Society for Social Pediatrics (ESSOP) and Committee on Public Education, American Academy of Pediatrics and reinforced, it should not be eliminated.

Zalkind HJ, Allen PW. Strengthening families: the role of community-based and grassroots organizations. *N C Med J* 2005; 66(5):383-5.

Zandi PP, Klein AP, Addington AM *et al.* Multilocus linkage analysis of the German asthma data. *Genet Epidemiol* 2001; 21 Suppl 1:S210-5. Abstract: We analyzed data from the German Asthma Genetics Group with three methods that utilize pedigree-specific nonparametric linkage scores to facilitate the search for multiple independent and interacting susceptibility loci. The three methods included a conditional analysis, logistic regression, and neural networks. Although there were differences, the three methods identified many of the same susceptibility loci. The most consistent evidence was provided for loci on chromosomes 1, 2, 6, 9, and 15. Both the conditional and the logistic regression analyses suggested an epistatic relationship between loci on chromosomes 2 and 9. The logistic regression analysis further revealed evidence for locus heterogeneity between loci on chromosomes 6 and 15. Finally, the neural network analysis identified a potential locus on chromosome 17 that was not identified in the other analyses.

Zanoti-Jeronymo DV, Carvalho AM. Self-concept, academic performance and behavioral evaluation of the children of alcoholic parents. *Rev Bras Psiquiatr* 2005; 27(3):233-6.

Abstract: OBJECTIVE: It has been shown that being the child of an alcoholic is a risk factor for the development of alcoholism in adulthood. Due to the suffering caused by living with alcoholic parents, other vulnerabilities appear in such children. Among these are low self-esteem, poor academic performance and behavioral problems. This work aims to comparatively evaluate children of alcoholic parents and children of nonalcoholic parents. METHODS: The study design was quasi-experimental, involving two comparison groups. Two groups of 20 children were selected. The groups consisted of 10- to 12-year-old male and female children. One group comprised children of alcoholic parents, whereas the other comprised children of nonalcoholic parents. The self-concepts of these children were evaluated using the Piers-Harris Children's Self-Concept Scale as well as the Academic Performance Test. Their mothers participated in the study by answering questions related to the behavior of their children on the Rutter A2 scale of Child Behavior. RESULTS: The results showed that the children of alcoholic parents tended to have more negative self-

concepts and presented lower academic performance in reading and arithmetic than did children of nonalcoholic parents. Based on the responses given by the mothers, the children of alcoholic parents presented more behavioral problems than did those of nonalcoholic parents. CONCLUSIONS: The results of this study confirm those of other studies and call attention to the need to be aware of the potential vulnerabilities of children of alcoholic parents and, especially, to try to minimize such vulnerabilities, thereby altering the course of psychological suffering that can mark their lives.

Zavela KJ. Developing effective school-based drug abuse prevention programs. *Am J Health Behav* 2002; 26(4):252-65.

Abstract: OBJECTIVE: To research effective drug prevention strategies for school-aged populations from drug prevention programs funded by the USDHHS Center for Substance Abuse Prevention (CSAP). METHOD: Nine directors and staff members from model CSAP-funded programs were interviewed. RESULTS: Fifteen strategies that focus on building trusted relationships, selecting well-qualified staff using existing communication networks, and providing timely evaluation feedback are discussed, with examples from the agencies cited. CONCLUSION: Formulating effective partnerships that support both the goals of the outside agency with drug prevention resources and the mission of a school can contribute toward effective school-based drug prevention programs.

Zebrowitz LA, Fellous JM, Mignault A, Andreoletti C. Trait impressions as overgeneralized responses to adaptively significant facial qualities: evidence from connectionist modeling. *Pers Soc Psychol Rev* 2003; 7(3):194-215.

Abstract: Connectionist modeling experiments tested anomalous-face and baby-face overgeneralization hypotheses proposed to explain consensual trait impressions of faces. Activation of a neural network unit trained to respond to anomalous faces predicted impressions of normal adult faces varying in attractiveness as well as several elderly stereotypes. Activation of a neural network unit trained to respond to babies' faces predicted impressions of adults varying in babyfacedness as well as 1 elderly stereotype. Thus, similarities of normal adult faces to anomalous faces or babies' faces contribute to impressions of them quite apart from knowledge of overlapping social stereotypes. The evolutionary importance of appropriate responses to unfit individuals or babies is presumed to produce a strong response preparedness that is overgeneralized to faces resembling the unfit or babies.

Zeigler VL. Ethical principles and parental choice: treatment options for neonates with hypoplastic left heart syndrome. *Pediatr Nurs* 2003; 29(1):65-9.

Abstract: Nurses caring for children with congenital heart disease face unique challenges, especially when caring for neonates diagnosed with hypoplastic left heart syndrome (HLHS). The treatment options for these neonates present difficult choices for the child's decision makers and are not without significant life-altering consequences. In order to assist in the decision-making process, nurses as patient and family advocates should acknowledge the unique role they play in the informed consent process, while simultaneously identifying specific ethical principles that are components of this process. By incorporating the principles of autonomy, beneficence, and veracity into specific nursing interventions, nurses can assist families in making informed decisions regarding a treatment option that is best for the child as well as the family.

Zeira A, Astor RA, Benbenishty R. School violence in Israel: findings of a national survey. *Soc Work* 2003; 48(4):471-83.

Abstract: The authors report preliminary findings of a national survey on school violence in Israel. The national representative sample was stratified on school type--elementary, middle, and high schools--and ethnicity--Jewish and Arab students. A total of 15,916 students from 603 classes and 232 schools participated in the study, resulting in a 91 percent response rate. Findings revealed high rates of violence in all areas and among all age groups, but relatively higher rates of low-level violent behaviors and lower rates of more severe violent events. The authors report on age-related, gender, and cultural differences and discuss social workers' roles in shaping national policy and professional discourse on school violence.

Zeira A, Astor RA, Benbenishty R. Sexual harassment in Jewish and Arab public schools in Israel. *Child Abuse Negl* 2002; 26(2):149-66.

Abstract: OBJECTIVE: Current empirical literature on sexual harassment in schools is mostly based on nonrepresentative samples of middle-class high-school Caucasian female students. Thus the scope of research regarding gender, age, and cultural differences is very limited. This article reports on findings on sexual harassment in Jewish and Arab schools in Israel with regard to gender, age, and cultural differences. METHOD: The study is part of the first national survey on school violence in Israel. The representative sample includes 10,400 students in grades 7 through 11 attending public schools in Israel. Students were asked to report whether they were victims of specific acts of sexual harassment in school during the month before the survey. RESULTS: Overall, 29.1% of the students were victims of at least one act of harassment. The more common acts were to show offensive pictures or to send obscene letters, to take off or to try to take off part of the student's clothing, and to try to kiss a student. The most vulnerable groups are the Arab boys and 8th grade students. Report rates were the lowest

among Arab girls. CONCLUSIONS: Sexual harassment is prevalent in Israeli schools. The pattern of victimization is different for boys and girls and for students in Jewish and Arab schools. These patterns are a complex phenomenon that must be considered in the intervention and policy measures addressing sexual harassment at school.

Zelnik N, Newfield RS, Silman-Stolar Z, Goikhman I. Height distribution in children with Tourette syndrome. *J Child Neurol* 2002; 17(3):200-4.

Abstract: Tourette syndrome is characterized by motor and vocal tics, frequently accompanied by attention-deficit hyperactivity disorder (ADHD), obsessive-compulsive disorder, coprolalia, aggressive or self-injurious behavior, and learning disabilities. We investigated the height distribution and clinical characteristics of 38 consecutive patients with Tourette syndrome. Seventeen patients with Tourette syndrome (44.7%) were in the lower height quartile versus 25% from a control group of 44 patients with ADHD ( $P < .05$ ). The mean standard deviation score differential (patient height - [target height]) was  $-1.12 \pm 0.82$  for patients in the first quartile (group A) compared with  $0.42 \pm 0.63$  in taller patients with Tourette syndrome (group B) ( $P < .001$ ). The mean birthweight of boys in group A versus group B was  $3023 \pm 351$  g and  $3363 \pm 486$  g, respectively ( $P < .02$ ); birthweight correlated with standard deviation score ( $r = .43$ ). Current weight relative to height was normal. Conduct disorder and/or self-injurious behavior were more common in group A patients ( $P < .05$ ). Relative short stature appears common in Tourette syndrome, and its presence with other features may implicate a neurotransmitter system that interacts with neuroendocrine pathways, controlling height.

Zerquera JT, Alonso MP, Bejerano GL, Lopez JO, Rodriguez NA. Assessment of the doses received by the Cuban population from 40K contained in the body: modelling based on a neural network. *Radiat Prot Dosimetry* 2003; 104(3):237-43.

Abstract: Potassium-40 constitutes the main natural source of potassium present in the body, which influences the effective dose received by people. With the aim of assessing the contribution of this component to the doses received by the Cuban population, a study intended to assess the doses was developed. For this purpose, a representative sample of the Cuban population was selected according to age and sex. The measurements were made using the whole-body counter (WBC) of the Center for Radiation Protection and Hygiene (CPHR). For dose estimations, a uniform distribution of potassium for the whole body was assumed. The methodology used was the one recommended by the ICRP. The values of annual effective dose range between 93 and 209 microSv for females and between 123 and 212 microSv for males. The annual average effective dose for members of the public was estimated as  $150 \pm 40$  microSv, taking

into account the experimental data and the specific features of the Cuban population. With the dose values obtained, it was possible to model dose estimates by means of a neural network, which was trained with the results obtained and using as starting data the sex, age, height and corporal weight of people studied. The model obtained allows consideration of the anatomical features of each person in the estimation of doses.

Zilberman ML, Blume SB. [Domestic violence, alcohol and substance abuse]. *Rev Bras Psiquiatr* 2005; 27 Suppl 2:S51-5.

Abstract: Domestic violence and substance abuse are common in primary care patients. Although these problems are associated with severe physical and psychological sequelae, they are often undiagnosed. This article provides an overview of the prevalence of these problems, the health-related consequences for adults, children and elderly, as well as the challenges for clinicians in screening, assessment and referral.

Zimba EW, McInerney PA. The knowledge and practices of primary care givers regarding home-based care of HIV/AIDS children in Blantyre (Malawi). *Curationis* 2001; 24(3):83-91.

Abstract: Knowledge is one of the major factors that promotes adherence to treatment regimens. With the current trends worldwide of home and community-based services for the management of HIV/AIDS patients, knowledge of care givers about the home care of these patients will determine the success of the programs. The purpose of this descriptive study was to explore the knowledge and practices of primary care givers of HIV/AIDS children in the provision of home care services. In this study an attempt was made to describe the factors which are associated with knowledge. Thirty-six primary care givers were randomly selected from three major home based care centres in Blantyre City, Malawi. A structured interview schedule was used to collect data. Data were analysed manually and by computer, using the Statistical Package for Social Science (SPSS). The findings revealed a gap in knowledge since in many instances taking a child to the hospital for the management of minor ailments was the action of choice, thus perpetuating the problem of overburdening hospital resources. Lack of prior preparation for home based care was found to be the major factor contributing to the lack of knowledge. Recommendations proposed include the need to put into place mechanisms that will ensure that all the primary care givers are adequately prepared in good time for home care service. Ensuring regular home visits was also thought to be helpful for efficient and effective supervision and reinforcement of information given to fill the gaps in knowledge wherever necessary.

Zink T, Elder N, Jacobson J, Klostermann B. Medical management of intimate partner violence considering the stages of change: precontemplation and contemplation. *Ann Fam Med* 2004; 2(3):231-9. Abstract: BACKGROUND: We undertook a study to understand how women who are victims of intimate partner violence (IPV) want physicians to manage these abusive relationships in the primary care office. METHODS: Thirty-two mothers in IPV shelters or support groups in southwestern Ohio were interviewed to explore their abuse experiences and health care encounters retrospectively. The interviews were taped and transcribed. Using thematic analysis techniques, transcripts were read for indications of the stages of change and for participants' desires concerning appropriate physician management. RESULTS: Participants believed that physicians should screen women for IPV both on a routine basis and when symptoms indicating possible abuse are present, even if the victim does not disclose the abuse. Screening is an important tool to capture those women early in the process of victimization. When a victim does not recognize her relationship as abusive, participants recommended that physicians raise the issue by asking, but they also warned that doing more may alienate the victim. Participants also encouraged physicians to explore clues that victims might give about the abuse. In later contemplation, victims are willing to disclose the abuse and are exploring options. Physicians were encouraged to affirm the abuse, know local resources for IPV victims, make appropriate referrals, educate victims about how the abuse affects their health, and document the abuse. Participants identified a variety of internal and external factors that had affected their processes. CONCLUSIONS: In hindsight, IPV victims recommended desired actions from physicians that could help them during early stages of coming to terms with their abusive relationships. Stage-matched interventions may help physicians manage IPV more effectively and avoid overloading the victim with information for which she is not ready.

Zink T, Kamine D, Musk L, Sill M, Field V, Putnam F. What are providers' reporting requirements for children who witness domestic violence? *Clin Pediatr (Phila)* 2004; 43(5):449-60.

Abstract: Each year, 3.3 to 10 million children are exposed to domestic violence/abuse (DV). Providers' reporting obligations for these children are unclear. The child maltreatment statutes available on state's web sites (through August 2003) were reviewed. Only Alaska defines DV in the presence of a child as child abuse within its juvenile code. Within their child abuse definition and reporting statutes, many states include language such as "substantial risk" or "imminent danger" of "physical harm" or "mental injury." Although knowledge of the state law is an important first step, abiding by it may be challenging because most statutes are open to wide interpretation. As a result, providers are encouraged to seek advice from

local child maltreatment specialists who understand the local legal interpretations and resources.

Zink T, Sill M. Intimate partner violence and job instability. *J Am Med Womens Assoc* 2004; 59(1):32-5. Abstract: OBJECTIVE: Research has shown that intimate partner violence (IPV) affects the physical and mental health of victims. It can also compromise work performance, leading to job loss. We explored the potential link between job loss and IPV as part of a larger study on IPV and health care. METHODS: Thirty-two mothers in Midwestern IPV shelters or support groups were interviewed to gather information about their abuse histories, health care experiences, and demographic characteristics. Interviews were audio taped, transcribed, and reviewed for themes. RESULTS: Half of participants had lost jobs because of IPV. Reasons included: the abuser told the victim to quit, in order to be safe, excessive absences because of covering up the abuse, and health issues exacerbated by IPV. CONCLUSION: Job instability was common among IPV victims in this study. Although this study did not address cause and effect, evidence of job instability may be another "red flag symptom" indicating that providers should screen for IPV.

Zipitis CS, Paschalides C. Caring for a child with spina bifida: understanding the child and carer. *J Child Health Care* 2003; 7(2):101-12. Abstract: Spina bifida is a common congenital abnormality, which causes significant physical and psychological morbidity in affected children and which also affects their carers. This small-scale study looked at the health problems of a child with a myelomeningocele. It also addresses the psychosocial problems that his mother, his main carer, faced and the social networks involved in his care. The evidence supporting various aspects of spina bifida prevention and management is explored. Furthermore, a literature review is included, with regards to physical and psychological issues for child and carer. This study aims to raise awareness of the problems faced by children with myelomeningocele and their families. In particular, we aim to educate health care professionals on the importance of perceived stress by carers of such children, and suggest ways to reduce psychosocial morbidity.

Zwaigenbaum L, Bryson S, Rogers T, Roberts W, Brian J, Szatmari P. Behavioral manifestations of autism in the first year of life. *Int J Dev Neurosci* 2005; 23(2-3):143-

52.

Abstract: In the interest of more systematically documenting the early signs of autism, and of testing specific hypotheses regarding their underlying neurodevelopmental substrates, we have initiated a longitudinal study of high-risk infants, all of whom have an older sibling diagnosed with an autistic spectrum disorder. Our sample currently includes 150 infant siblings, including 65 who have been followed to age 24 months, who are the focus of this paper. We have also followed a comparison group of low-risk infants. Our measures include a novel observational scale (the first, to our knowledge, that is designed to assess autism-specific behavior in infants), a computerized visual orienting task, and standardized measures of temperament, cognitive and language development. Our preliminary results indicate that by 12 months of age, siblings who are later diagnosed with autism may be distinguished from other siblings and low-risk controls on the basis of: (1) several specific behavioral markers, including atypicalities in eye contact, visual tracking, disengagement of visual attention, orienting to name, imitation, social smiling, reactivity, social interest and affect, and sensory-oriented behaviors; (2) prolonged latency to disengage visual attention; (3) a characteristic pattern of early temperament, with marked passivity and decreased activity level at 6 months, followed by extreme distress reactions, a tendency to fixate on particular objects in the environment, and decreased expression of positive affect by 12 months; and (4) delayed expressive and receptive language. We discuss these findings in the context of various neural networks thought to underlie neurodevelopmental abnormalities in autism, including poor visual orienting. Over time, as we are able to prospectively study larger numbers and to examine interrelationships among both early-developing behaviors and biological indices of interest, we hope this work will advance current understanding of the neurodevelopmental origins of autism.

Zwick EB, Leistriz L, Milleit B *et al.* Classification of equinus in ambulatory children with cerebral palsy-discrimination between dynamic tightness and fixed contracture. *Gait Posture* 2004; 20(3):273-9. Abstract: In this study a generalised dynamic neural network (GDNN) was designed to process gait analysis parameters to evaluate equinus deformity in ambulatory children with cerebral palsy. The aim was to differentiate dynamic calf muscle tightness from fixed muscle contracture. Patients underwent clinical examination and had instrumented gait analysis before evaluating their equinus under anaesthesia and muscle relaxation at the time of surgery to improve gait. The performance of the clinical examination, the subjective interpretation of gait analysis results, and the application of the neural network to assess ankle function were compared to the examination under anaesthesia. Evaluation of equinus by a Neural Network showed high sensitivity and specificity values

with a likelihood ratio of +14.63. The results indicate that dynamic calf muscle tightness can be differentiated

from fixed calf muscle contracture with considerable precision that might facilitate clinical decision-making.
